ERRATA FOR VOLUME XCIX OF THE OFFICIAL GAZETTE.

ANNOUNCEMENTS—VOLUME XCIX.

DISCLAIMERS—VOLUME XCIX.

TEXT OF THE OFFICIAL GAZETTE, APRIL 1 TO JUNE 30, 1902, INCLUSIVE.

INDEX TO THE DECISIONS OF THE COMMISSIONER OF PATENTS AND OF THE UNITED STATES

COURTS IN PATENT CASES.

DIGEST OF DECISIONS OF THE COMMISSIONER OF PATENTS AND OF THE UNITED STATES

COURTS IN PATENT CASES.

INDEX OF PATENTS AND PATENTERS FOR THE QUARTER YEAR, APRIL TO JUNE, 1902.

ERRATA.

666,702, page 127, in heading, assignment, for "assignor to himself, and Franklin K. Young and Michael P. Curran, Trustees," read *assignor to himself, Franklin K. Young, and Michael P. Curran, Trustees.*

667,589, page 509, in heading, title of invention, for "Electric Fan" read *Electric Motors.*

668,402, page 843, in heading, assignment, name of assignee, for "Steam Carriage Boiler Company" read *Steam Carriage Boiler Company.*

666,541, page 913, in heading, title of invention, for "Index-Card for Duplicate Whist" read *Index-Cards for Duplicate Whist.*

668,761, page 1015, in heading, date of filing application, for "Aug. 6, 1901," read *Aug. 6, 1900.*

669,818, page 1402, in heading, patent number, for "669,818" read *699,818.*

701,450, page 2109, in heading, residence of patentee, for "North Manchester, England," read *Eccles, near Manchester, England.*

701,948, page 2373, second claim, line 2, for the article "an" read *in.*

702,208, page 2496, in heading, title of invention, for "Playing-Card" read *Playing-Cards.*

702,399, page 2608, first claim, line 1, for the word "sort" read *source.*

702,371, page 2524, in heading, after residence of patentee, insert *assignor to The Wolf Electrical Promoting Company of Cincinnati, Ohio, a Corporation of Ohio.*

702,378, page 2528, in heading, assignment, name of assignee, for "Bertha E. Ranzel" read *Bertha E. Ranzel.*

702,473, page 2589, in heading, for the words "(No model.)" read *(Model.)*

702,617, page 2646, first claim, line 9, for the word "levers" read *leaves.*

702,125, page 2606, in heading, title of invention, for "Insulating Electric Conductor" read *Insulating Electric Conductors.*

702,358, page 2961, eighteenth claim, line 4, for the word "mold" read *frame*; page 2952, fortieth claim, line 1, for the word "grooves" read *groove*, and page 2953, forty-seventh claim, line 5, for the word "can" read *dam.*

28,106, (trade-mark,) page 658, in heading, name of registrant, for "The Goldsmith, Joseph Fels Co." read *The Goldsmith, Joseph, Fels Co.*

28,257, (trade-mark,) page 2006, claim, last line, date of use, for "January 1902" read *January 1901.*

Commissioner's Decisions, page 448, second column, line 23 from bottom of the page, for "94 O. G., 147" read *84 O. G., 147.*

Classification Bulletin.

DEPARTMENT OF THE INTERIOR,
UNITED STATES PATENT OFFICE,
Washington, D. C., March 11, 1902.

Orders revising classification will be published as a CLASSIFICATION BULLETIN. The first issue of this BULLETIN forms No. 5 of a series of which the preceding numbers appeared in Vols. 91, 92, 93, and 97 of the OFFICIAL GAZETTE.

These BULLETINS are sold by the Office at ten cents per copy.
F. I. ALLEN,
Commissioner.

Prohibiting Changes in Office Papers.

(ORDER NO. 1,424.)

DEPARTMENT OF THE INTERIOR,
UNITED STATES PATENT OFFICE,
Washington, D. C., February 4, 1902.

It is hereby ordered that no erasures be made or any note, interlineation, or other mark in pencil or otherwise, except by formal amendment duly signed, in the body or written portions of the specification or of any other paper filed in an application for patent.

It is further directed that no change be made by any person in any record of this Office without the written approval of the Commissioner of Patents.

Attorneys, employees of the Patent Office, and all others will be held to strict accountability for any violation of this order.

F. I. ALLEN,
Commissioner.

APPLICATIONS UNDER EXAMINATION.

Condition at Close of Business March 25, 1902.

Room No.	Divisions and subjects of invention.	Oldest new application and oldest action by applicant awaiting office action.		No. of applications awaiting action.
		New.	Amended	
In arrears—Under one month.

Indexes to Periodicals.

The following journals containing indexes to periodical literature may be found on file in the reading-room of the Scientific Library:

- Electrical World and Engineer*, a weekly digest of electrical articles.
- Engineering Digest*, a monthly title-index of engineering articles in the English language only.
- Journal of the United States Artillery*, a bimonthly title-index of current artillery literature.
- Railroad Digest*, a monthly synopsis of universal railroad literature.
- School of Mines Quarterly*, a quarterly synoptical index of articles on analytical chemistry and title-index of metallurgical literature.
- Science Abstracts*, physics and electrical engineering. Monthly abstracts of the principal articles on physics published in the American and foreign journals.

Names of Applicants.

When the full first name of the applicant does not appear either in his signature or in the preamble to the specification, the Examiner will, in his first official letter, require an amendment supplying the omission, and he will not pass the application to issue until the omission has been supplied, unless an affidavit shall have been filed setting forth that the full first name of the applicant is the one originally given by him.

PATENTS

GRANTED APRIL 1, 1902.

696,893. STENCIL-PRINTING MACHINE. JAMES A. ANGLER.
Hatch, Mass. Filed June 20, 1900. Serial No. 31,404. (No model.)

Claim.—1. In a stencil-printing machine, a carrier having a substantially imperforate supporting-surface, an ink-holding pad composed of a thick blanket adapted to be saturated to retain a comparatively large quantity of ink, and supported by said surface, a stencil-sheet superposed on said pad and formed of textile material, the pad when subjected to pressure delivering its ink through the stencil-sheet.

2. In a stencil-printing machine, a carrier, a connected pad-holder having a substantially imperforate surface to receive a pad adapted to be saturated with ink, said pad when subjected to pressure delivering ink to a stencil-sheet, said stencil-sheet being formed of textile material and superposed on said pad.

3. In a stencil-printing machine, a carrier, a pivoted pad-holder having a pad-holding chamber and mounted on said carrier, and locking means to confine said carrier in working position.

4. In a stencil-printing machine, a carrier, a pad adapted to be saturated with ink and a pivoted pad-holder having an imperforate supporting-surface to contain said pad and means for connecting said pad to said holder.

5. In a stencil-printing apparatus, a pad adapted to be saturated with ink, means to hold one end of said pad in fixed position, and a device located at the opposite end of said pad to enable the same to be stretched uniformly when the pad is being applied to the apparatus.

6. In a stencil-printing machine, a carrier having an imperforate supporting-surface, a saturated pad cooperatively connected therewith and a stencil-sheet formed of textile material, a frame having slotted bearings, and a roller having its journals entering said bearings, means connecting with said journals to support said roller and frame yieldingly, said roller rolling over the outer surface of the sheet being printed forcing it against the stencil-sheet on said pad depressed by said frame moving the roller away from the path of movement of said pad.

7. In a stencil-printing machine, a suitable rotative carrier, a connected pad-holder and stencil-sheet support, a suitable cam movable with said carrier, a sheet-delivery table, a roller depressed intermittently by the direct contact of the cam of the carrier therewith to enable the leading end of the sheet about to be printed to be fed between the roller and the leading end of the movable pad-holder, and means to move said roller and cause it to impinge the paper to be printed between itself and said pad-holder, said roller cooperating with said pad-holder to feed and effect the printing of the sheet and its delivery from the machine.

8. A stencil-sheet composed of woven material coated with a substance impervious to ink and capable of being stretched or distorted to enable ink to pass through the stencil-sheet and imprint the stencil characters upon paper, and an attached body layer upon which the sheet is mounted and a backing to said body layer to prevent stretching.

9. A stencil-sheet composed of a thin textile fabric coated with a substance impervious to ink, a body layer of soft absorbent material reinforcing said sheet to prevent stretching thereof, and an ink-holding pad on which said body layer of absorbent material and stencil-sheet are superposed.

10. In a stencil-printing machine, a carrier having an imperforate supporting-surface, an ink-holding pad movable therewith and composed of a thick blanket adapted to be saturated with a comparatively large quantity of ink, means to contain the pad on the supporting-surface of the carrier, the pad containing at its outer side a stencil-sheet, and means to contain the sheet to be printed upon, the pad when subjected to pressure during the action of printing delivering its contained ink through the stencil-sheet.

11. In a stencil-printing machine, a carrier having a substantially imperforate supporting-surface, an ink-holding pad movable therewith and composed of a thick blanket adapted to be saturated with a comparatively large quantity of ink, means to contain the pad at the exterior of the carrier, the pad containing at its outer side a stencil-sheet, a sheet of textile material interposed between the pad and the stencil-sheet, and means to contain the sheet to be printed upon, the pad when subjected to pressure during the action of printing delivering its contained ink through the stencil-sheet.

696,894. COMBINED WINDLASS AND WARPING-WINCH. JACOB R. ANDERSON, Bath, Me. Filed Jan. 20, 1902. Serial No. 31,369. (No model.)

Claim.—In combination with the windlass and the worm-gear upon its shaft, a shaft as 3 having a worm 10 in mesh with the gear upon the windlass-shaft, a second worm 9 on the same shaft, a shaft 6 carrying winch-heads and provided with a worm-gear 8 in mesh with the second worm on the main driving-shaft 3, all substantially as described.

696,895. WIRE STRETCHER AND CUTTER. JAMES A. ANDERSON.
Baldwin, Kans. Filed Dec. 10, 1901. Serial No. 30,140. (No model.)

Claim.—1. A wire stretching and cutting apparatus, comprising in combination with a frame, a shaft journaled thereon, a reel on said shaft, a ratchet-wheel rotating with said reel, a stationary and a pivoted shearing-blade, an angle-lever for tilting said pivoted shearing-blade, a long-

radially-movable bar pivoted at one end to said angle-lever and a pawl hinged to said bar and adapted to engage said ratchet-wheel and means for rotating the reel on which a wire is designed to be wound the tension of which is adapted to estimate the pivoted shearing-blade, as set forth.

2. An apparatus for stretching and cutting wire, comprising in combination with the frame, a shaft journaled therein, a ratchet-wheel and pawl engaging the same, geared wheels and means for rotating the shaft, a fixed shearing-blade, fastened to the frame, a pivoted blade, mounted on the frame and adjacent to said fixed blade, an angle-lever pivoted to the frame and having one end positioned underneath said pivoted shearing-blade, a sliding link pivoted at one end to said angle-lever, a pawl hinged to the other end of said link, adapted to be thrown into engagement with the teeth of the ratchet-wheel on said shaft, and a spring secured at one end, to the frame, and its other end to said link, as shown and described.

696,896. MACHINE FOR PULVERIZING AND SEPARATING LIME. OLEY M. AVERY, Chicago, Ill., assignor to the Chisholm, Boyd & White Company, a Corporation of Illinois. Filed Nov. 1, 1900. Serial No. 26,108. (No model.)

Claim.—1. In a machine for pulverizing lime, an inclined revolving barrel, having a perforate portion near the lower end thereof constituting a screen, and means for supplying steam to said barrel, in combination with a hopper beneath said perforate portion, and a removable head at the lower end of said barrel for permitting the removal of material from said barrel.

2. In a machine for pulverizing lime, an inclined revolving barrel, having a perforate portion near the lower end thereof, constituting a screen, and means for supplying steam to said barrel, in combination with a stationary head for closing the receiving extremity of said barrel, a spout connected to said head for introducing lime into said barrel, a door in said spout hinged near its upper extremity and opening inwardly toward said barrel, and means for closing the opposite extremity of said barrel.

3. In a machine for pulverizing lime, the combination of an inclined revolving barrel the lower portion whereof constitutes a screen, a pipe for introducing steam into said barrel, a hopper beneath said screen, a housing over said screen, means for introducing lime into the upper extremity of said barrel, and a removable head at the lower extremity of said barrel.

4. In a machine for pulverizing lime, the combination of a revolving barrel, means for supplying steam thereto, other means for closing the receiving extremity of said barrel, and a front head for closing the discharging extremity of said barrel, said front head being movable away from said barrel thereby permitting the removal of material therefrom.

5. In a machine for pulverizing lime, the combination of a closed

revolving barrel, means for supplying steam thereto, and means for suspending and revolving said barrel.

6. In a machine for pulverizing lime, the combination of a closed revolving barrel means for supplying steam thereto, tracks or guides encircling said barrel, chains running upon said tracks or guides and suspending said barrel, and wheels located above said barrel for suspending said chains.

7. In a machine for pulverizing lime the combination of a revolving barrel, means for supplying a heated fluid thereto, a main driving shaft, means for suspending said barrel from said shaft and friction-gears for driving said shaft.

8. In a machine for pulverizing lime, the combination of a revolving barrel, means for supplying steam thereto, a main driving-shaft, means for suspending said barrel from said shaft, friction-gears for driving said shaft, and an eccentric bearing whereby the driving friction-gear may be moved into and out of engagement with the driven friction-gear.

9. In a combined pulverizing and separating machine for lime, the combination of a vessel for receiving the lime, said vessel having a perforated portion constituting a screen or screen for permitting the escape of pulverized material, means for agitating said vessel, and means for supplying a heated fluid thereto.

10. In a pulverizer and separator for lime, the combination of a revolving barrel suitably closed at the ends, and having its axis inclined to the horizontal, a screen constituting a portion of said barrel located at the lower end thereof, a housing enclosing the screen portion of said barrel and means for supplying steam to said barrel.

11. In a pulverizer and separator for lime, the combination of a closed revolving barrel, the axis whereof is inclined, said barrel being perforated near the lower extremity thereof for screening the contents of said barrel, a housing over said perforated portion of said barrel, a second housing enclosing said barrel and said inner housing, and means for supplying steam to said barrel.

12. In a pulverizer for lime, the combination of a barrel, means for introducing steam thereto, chains for supporting said barrel, and traction or driving wheels for supporting and driving said chains, said wheels having beveled rims, and said chains having links fitting over said wheels and wedging upon the rims thereof substantially as described.

13. In a pulverizer for lime, the combination of a revolving barrel, means for introducing steam thereto, chains for suspending said barrel, means for supporting said chains, and guide-wheels for guiding said chains thereby determining the angle of inclination thereof.

14. In a lime-separator, the combination of a closed revolving barrel perforated at one portion to form a screen a housing over said screen, a removable head to said barrel, a hopper under said screen and connecting with said housing, an auxiliary screen beneath said removable head, said screen also connecting with said hopper, and means for supplying steam to said barrel.

15. In a machine for pulverizing lime, the combination of a revolving barrel, having a perforate portion constituting a screen, means for supplying steam to said barrel means for temporarily closing the extremities of said barrel, a hopper beneath the screen portion of said barrel, and a secondary screen beneath one extremity of said barrel, and above a portion of said hopper.

696,897. FRAME FOR SELF-PROPELLED VEHICLES. AUGUST A. BALL, JR., Lynn, Mass., assignor to Elton Thomson, Swampscott, Mass. Filed Dec. 11, 1901. Serial No. 95,462. (No model.)

Claim.—1. In a vehicle, the combination of a front and a rear axle, a body, a frame rigidly secured to one axle and pivotally secured to the

other, and a second frame rigidly secured to one axle and pivotally secured to the body.

2. In a vehicle, the combination of a front and a rear axle, a body, springs located between the vehicle-body and the axles, a frame rigidly secured to one axle and pivotally secured to the other, and a second frame rigidly secured to one axle and pivotally secured to the spring-supported body.

3. In a vehicle, the combination of a front and a rear axle, a body, a U-shaped frame rigidly secured to one axle and pivotally secured to the other, and a triangular frame pivotally secured at its apex to the vehicle-body, and rigidly secured at its ends to the other axle.

4. In a vehicle, the combination of a front and a rear axle, a body, springs between the body and the axles, a frame rigidly secured to one axle and pivotally secured to the other, a second frame rigidly secured to one axle, and a pivotal support for the second frame mounted on the vehicle-body at approximately its center of gravity.

5. In a vehicle, the combination of a driving and a driven axle, a body, springs located between the body and the axles, a frame rigidly secured to the driven axle and pivotally secured to the driving-axle, a second frame rigidly secured to the driving-axle and pivotally secured to the spring-supported body, and a bar which is connected to the driving-axle and to the pivotal connection on the body and forms a brace between them.

6. In a vehicle, the combination of a body, front and rear axles, springs between the body and the axles, a frame rigidly secured to the rear axle, a half-and-whisker connection for securing the frame to the body, and a bar which is secured to the rear axle at one end and to the half-and-whisker connection at the other.

7. In a vehicle, the combination of a body, front and rear axles, springs between the body and the axles, a frame rigidly secured to the rear axle, a half-and-whisker connection for securing the frame to the body, a yoke in the rear axle for including the differential gearing, and a bar which is secured to the half-and-whisker connection at one end and to the yoke at the other.

8. In a vehicle, the combination of a body, front and rear axles, springs between the body and the axles, a frame rigidly secured to the rear axle, an engine, a half-and-whisker joint for securing the frame to the body, one portion of said joint being secured to the vehicle-body, the other being secured to the engine, a yoke in the rear axle, a connection between the yoke and the engine, and a bar which is secured to the yoke and to that portion of the half-and-whisker joint which is carried by the engine.

9. In a vehicle, the combination of a body, front and rear axles, springs between the body and the axles, a frame rigidly secured to the rear axle, an engine, a universal connection between the engine and the body, one portion of said connection being carried by the body, the other by the engine, a bar which is secured to the rear axle at one end, and a clamp for the opposite end of the bar which is mounted on that portion of the connection carried by the engine.

10. In a vehicle, the combination of front and rear axles, a body, springs between the body and the axles, an engine, a universal connection between the engine and the body, one portion of which is mounted on the engine, the other on the body, an axle-yoke, a distance-bar secured thereto, a pair of frame-bars rigidly secured to the rear axle, and a clamp mounted on the engine portion of the connection to which the distance and frame bars are secured.

11. In a vehicle, the combination of front and rear axles each provided with a straight and an arched member, a body, a frame which is rigidly secured to the arched member of the front axle and pivotally secured to the arched member of the rear axle, a second frame which is rigidly secured to the rear axle, and pivotally secured to the vehicle-body, springs for the body, and clamps for securing certain of the springs to the arched member of the rear axle, the said clamps permitting a certain amount of independent movement.

12. In a vehicle, the combination of a spring, an axle, rollers mounted thereon, a support for the spring, a segmental cleave, and a U-shaped clamp for holding the support and cleave in place.

696,898. ARMATURE-COIL. ANA F. BARNHARTER, Schenectady, N. Y., assignor to the General Electric Company, a Corporation of New York. Filed Dec. 2, 1900. Serial No. 95,388. (No model.)

Claim.—1. A coil for the armature of a dynamo-electric machine, composed of turns each containing a plurality of wires side by side.

2. A coil for the armature of a dynamo-electric machine, composed of multiple wires lying straight and parallel.

3. A coil for an armature, composed of superposed turns each composed of a plurality of insulated wires lashed together in longitudinal form.

4. An electric-machine coil having a plurality of turns, each of which is composed of a plurality of insulated wires laid side by side and a lashing of insulating material binding them together.

5. A coil for an electric machine, which is composed of turns consisting of a plurality of wires held rigidly together side by side to form a flat turn, said turns being laid flatwise one upon another to fill the winding-space.

696,899. CORK-EXTRACTOR. ALBERT BARNHARTER, Prospect, Ill. Filed Feb. 1, 1901. Serial No. 45,948. (No model.)

Claim.—1. In a cork-extractor, the combination with a suitable frame or casing, a longitudinally-movable cork-screw therein, a part non-revolubly held in said casing and for causing the rotation of said cork-screw during a part of its longitudinal travel, and a lever for imparting movement to said cork-screw, of an ejector positioned to engage the cork after withdrawal of the cork from the bottle, said ejector having a positive movement imparted thereto by one of the parts of the operating mechanism.

2. In a cork-extractor, the combination with a suitable frame or casing, a longitudinally-movable cork-screw therein, a part non-revolubly held in said casing and for causing the rotation of said cork-screw during a part of its longitudinal travel, and a lever for imparting movement to said cork-screw, of an ejector positioned to engage the cork after withdrawal of the cork from the bottle, said ejector having a positive movement imparted thereto by the operating-lever.

3. In a cork-extractor, the combination with a suitable frame or casing, a longitudinally-movable cork-screw therein, a part non-revolubly held in the casing, for causing the rotation of said cork-screw during a part of its longitudinal travel, and a lever for imparting movement to said cork-screw, of an ejector carried by the operating-lever.

4. In a cork-extractor, the combination with a suitable frame or casing, a longitudinally-movable cork-screw therein, a part non-revolubly held in the casing, for causing the rotation of said cork-screw during a part of its longitudinal travel, and a lever for imparting movement to said cork-screw, of a movable ejector-arm on the operating-lever.

5. In a cork-extractor, the combination with a suitable frame or casing, a longitudinally-movable cork-screw therein, a part non-revolubly held in the casing, for causing the rotation of said cork-screw during a part of its longitudinal travel, and a lever for imparting movement to said cork-screw, of a movable ejector-arm integrally formed on the operating-lever.

6. In a cork-extractor, the combination with a suitable frame or casing, a longitudinally-movable cork-screw therein, a part non-revolubly held in the casing, for causing the rotation of said cork-screw during a part of its longitudinal travel, and a lever for imparting movement to said cork-screw, of a movable ejector-arm on the operating-lever, said lever being pivotally maintained and having a shifting fulcrum and whereby a differential movement will be imparted to the ejector-arm and the carrier to cause said arm to be withdrawn from the path of travel of said movable part during the initial upward shift of the free end of the operating-lever.

7. In a cork-extractor, the combination with a suitable frame or casing, a longitudinally-movable cork-screw therein, a part non-revolubly held in the casing, for causing the rotation of said cork-screw during a part of its longitudinal travel, and a lever for imparting movement to said cork-screw, of a movable ejector-arm on the operating-lever, elongated hori-

legs wherein said lever is pivotally contained, and whereby a differential movement will be imparted to the ejector-arm and the carrier to cause said arm to be withdrawn from the path of travel of said movable part during the initial upward shift of the free end of the operating-lever.

8. In a cork-extractor, the combination with a suitable frame or casing, a longitudinally-movable corkerow therein, a part non-revolubly held therein for causing the rotation of the corkerow, of a positively-shifted ejector, means whereby the ejector is positively shifted, a bottle-holding device comprising jaws, a pivot for said jaws, and a receptacle for receiving and retaining the corks, said receptacle being pivotally contained by said pivot.

9. In a cork-extractor, the combination with a suitable frame or casing, of a longitudinally-movable carrier in said casing, a corkerow journaled in said carrier, a nut non-revolubly held in said casing, said nut having a limited longitudinal movement in said casing, a sliding connector, two latches carried by said connector, a cam integrally formed on each of the side walls of the casing for withdrawing said latches, respectively, and an operating-lever for imparting movement to said carrier.

696,400. SEWING-MACHINE. WILLIAM H. BENT, Griffin, Ga. Filed May 18, 1901. Serial No. 88,988. (No model.)

Claim.—As an improved article of manufacture, sewing-machine driving mechanism adapted to be applied directly to any ordinary sewing-machine, consisting of a lever adapted to be fulcrumed at its lower end to the reversed treadle of a sewing-machine, and a pitman movably secured midwise to the lever at one end, and adapted at its other end to be secured to the crank of the machine.

696,401. LATERAL ADJUSTOR FOR SURVEYING INSTRUMENTS. ORRISMAN L. BURDEN, Boston, Mass. Filed Sept. 26, 1901. Serial No. 78,516. (No model.)

Claim.—1. A lateral adjustor for surveying-instruments, comprising a guide-plate provided centrally with means for rigidly securing the same on a usual tripod, a slide-plate mounted thereon, said two plates being mutually provided with cooperating ways for maintaining accurate direction of movement, a thumb-screw in engagement with said two plates for accurately moving the top plate on the bottom plate, and means for mounting above said top plate a surveying-instrument.

2. A lateral adjustor for surveying-instruments, comprising a guide-plate provided centrally with means for rigidly securing the same on a usual tripod, a slide-plate mounted thereon, said two plates being mutually provided with cooperating ways for maintaining accurate direction of movement, a thumb-screw in engagement with said two plates for accurately

moving the top plate on the bottom plate, said top plate being provided on its upper side with guideways extending transversely to the direction of movement of said plate on the guide-plate below, a topmost guide-plate mounted on said guideways and shaped on its under surface to fit on said guideways, means for moving said topmost plate on said guideways, and means above said topmost plate for covering thereon the instrument proper.

3. In a surveying-instrument, means located between the instrument proper and the tripod for shifting the instrument bodily in one direction in a horizontal plane, and means for shifting said instrument bodily in a direction transversely thereto.

4. In a surveying-instrument, means located between the instrument proper and the tripod for shifting the instrument laterally in a horizontal plane, and means angularly shaped to indicate, by feeling, the extent of said lateral movement.

5. In a surveying-instrument, means located between the instrument proper and the tripod for shifting the instrument laterally in a horizontal plane, said means including a stationary part, a thumb-screw, and an indicator rotative therewith containing coarse spacing-points for enabling the operator to tell, by feeling, the extent of rotation of said screw by reference to a relatively stationary part.

6. A lateral adjustor for surveying-instruments, comprising a guide-plate provided centrally with means for rigidly securing the same on a usual tripod, a slide-plate mounted thereon, said two plates being mutually provided with cooperating ways for maintaining accurate direction of movement, a thumb-screw in engagement with said two plates for accurately moving the top plate on the bottom plate, an indicator, capable of readily indicating by feeling, carried by said thumb-screw for indicating the extent of rotation thereof, and means for mounting above said top plate a surveying-instrument.

7. A lateral adjustor for surveying-instruments, comprising a guide-plate provided centrally with means for rigidly securing the same on a usual tripod, a slide-plate mounted thereon, said two plates being mutually provided with cooperating ways for maintaining accurate direction of movement, a thumb-screw at each end of and in engagement with said two plates for accurately moving the top plate on the bottom plate, and means for mounting above said top plate a surveying-instrument.

8. A lateral adjustor for surveying-instruments, comprising a guide-plate provided centrally with means for rigidly securing the same on a usual tripod, a slide-plate mounted thereon, said guide-plate having its opposite side edges beveled, and said slide-plate having at its opposite edges depending portions beveled on their inner sides to rest on the beveled edges of the guide-plate, means retaining said two plates permanently together, independently-operable adjusting devices for adjusting the bearing-surfaces of the two plates with relation to each other, positive means for accurately sliding the top plate on the bottom plate, and means for mounting the instrument proper above the top plate.

9. A lateral adjustor for surveying-instruments, comprising a guide-plate provided centrally with means for rigidly securing the same on a usual tripod, a slide-plate mounted to slide on said guide-plate, guiding means for mutually guiding said plates in relative longitudinal movement, a transit proper mounted on said slide-plate and comprising usual telescope-leveling devices, &c., and means for positively moving the top plate on the bottom plate to any predetermined extent required.

696,402. PHOTOGRAPHIC FLASH-LIGHT MACHINE. LEONARD S. BIRLOW, St. Joseph, Mo. Filed July 26, 1901. Serial No. 68,981. (No model.)

Claim.—1. A flash-light pan provided with a cover retained in position over the powder during the explosion to spread and cause a flat flame.

2. A flash-pan and a cover therefor having notched ends as and for the purpose specified.

3. A flash-pan, and a cover therefor having notched ends and an intermediate slot, as shown and described.

4. A flash-pan and covers of different length and form fitted to said pan for use interchangeably to produce different styles of flame, as set forth.

5. A flash-pan and a rigid cover therefor slidable therein to cover the powder and remain rigid during the explosion to spread the flame, as set forth.

696,403. CAM-FASTENING FOR SHAFTS OF STAMP-MILLS. EDWARD A. BLANTON, JR., Wallingford, Pa., assignor to Blanton Patents Syndicate, Limited, London, England. Filed July 17, 1899. Serial No. 690,745. (No model.)

Claim.—1. The combination with a shaft, of a curved wedge secured against rotation thereon and having an outer face upon a curve the radii of which measured from the center of the shaft gradually increase, and a hub with an opening corresponding in part with and bearing on the face of the shaft and in part with and bearing on the entire outer face of the wedge, substantially as described.

2. The combination with a shaft, of a curved wedge secured against rotation thereon and having an outer face upon a curve the radii of which measured from the center of the shaft gradually increase, and a hub with an opening, a portion of which, not exceeding a semicircle, corresponds with and bears upon the face of the shaft, and a portion of the opening being curved and bearing on the entire outer face of the wedge, substantially as described.

3. The combination with a shaft, of a curved wedge secured against rotation thereon and having a face concentric to said shaft, and a hub with an opening corresponding in part with and bearing on the face of the shaft and in part with and bearing on the entire outer concentric face of the wedge, substantially as described.

4. The combination with a shaft, of a curved wedge secured against rotation thereon and having a face concentric to said shaft, and a hub with an opening, a portion of which, not exceeding a semicircle, corresponds with and bears on the face of the shaft and a portion of the opening being concentrically curved and bearing on the entire outer face of the wedge, substantially as described.

5. The combination with a cam-shaft having a series of eccentric bosses or wedges thereon arranged in different relative positions, of cams having hubs with openings corresponding in part with and bearing on the face of the shaft and in part with and bearing on the entire outer face of the eccentric bosses or wedges, the width of the cams approximating the width of the hubs, substantially as described.

696,404. CURTAIN-FIXTURE. WILLIAM E. BURGESS, Chicago, Ill. Filed July 10, 1901. Serial No. 67,770. (No model.)

Claim.—1. The herein-described curtain fixture or bracket, comprising a horizontal portion terminating at one end in a laterally-projecting elongated loop or slotted extension adapted to receive fastening devices driven into the upper edge of a window frame or casing, an inwardly-inclined pendant arm terminating in a bearing for one end of a shade-roller, a vertically-extending portion connecting the horizontal and inclined portions of the bracket, and an L-shaped curtain-pole hook connected with said vertical portion and extending outwardly therefrom.

2. A curtain fixture or bracket consisting of a metal strip a portion of which extends in a right line and is bent laterally at one end and then recurved and bent back parallel to itself to form an angular elongated extension adapted to receive the upper edge of a window-frame and receive fastening devices, said strip being bent downward from the outer end of the horizontal arm to form a vertical portion and thence inward and downward to form a pendant inclined arm the extremity of which is recurved to form a bearing for a shade-roller, and an L-shaped extension projecting outward from the vertical portion of the bracket to form a curtain-pole hook, substantially as described.

696,405. CLAMPING-WRENCH. RICHARD A. BUSH, Bridgeport, Conn. Filed Sept. 20, 1899. Serial No. 51,355. (No model.)

Claim.—1. In a clamp and wrench of the class described, the combination with a handle-bar having a fixed jaw, of a loose jaw free to slide on said bar and containing a pawl arranged to impinge the handle-bar, and further, to lift and force the jaw forward against the object engaged thereby.

2. In a clamp of the class described, a fixed jaw, a bar, a movable jaw having means to be drawn thereby against the clamping-bar and a pawl with roughened end surface to engage the smooth front side of said bar and adapted to force the sliding jaw toward the fixed one.

3. In an adjustable clamp, a fixed jaw and bar, a movable jaw upon said bar, a spring-actuated pawl pivoted within said jaw having a serrated face to engage the smooth edge of the bar, an adjustable screw in the back of the jaw adapted to engage the bar in a manner to force the pivot end of the pawl forward together with the jaw, toward the fixed jaw.

4. In a combined clamp and wrench, the combination of a bar carrying a fixed and a slidable jaw, of a pivoted pawl secured within the latter having a swinging, impinging and segmentally-shaped surface for engagement with the front edge of the bar and a screw at the rear end of the jaw to draw the movable jaw against the bar and also toward the fixed jaw, and finally to secure the jaw to the bar.

5. In a combined clamping-wrench of the class described, the combination with the jaw having a handle-bar secured thereon, of a jaw movably mounted upon said bar, a pawl pivotally mounted within said movable jaw and provided with a segmental serrated face, a spring to hold the operative end of the pawl in engagement with the bar, a screw adjustably mounted in the back of the jaw and arranged to firmly secure the jaw to the bar and simultaneously acting in conjunction with the pawl to provide a forward thrust to the operative end of said jaw.

696,406. WRENCH. RICHARD A. BUSH, Bridgeport, Conn. Filed June 5, 1901. Serial No. 68,265. (No model.)

Claim.—1. A wrench composed of a bar and a jaw fixed thereto, a jaw adapted to freely slide on said bar, a transverse circular plug passing

ing through the lower front portion of said jaw, and having a flattened side, with a series of teeth in line with the shank-cavity, a downwardly and rearwardly inclined plug having a series of teeth on its engaging end situated in a seat of the back portion of said movable jaw, a spring-actuated headed pin located in the lower rear part of said movable jaw and a cap enclosing said pin and spring.

2. In a wrench, the combination of a sliding jaw having on its lower front portion a circular plug with a flattened roughened side surface in line with the shank-cavity therein, a hole in its lower rear portion containing a spring-actuated plug, a cap to retain said plug and spring, a second circular plug in the upper rear portion with a roughened end surface also in line with the shank-cavity.

3. A wrench composed of a bar having a jaw secured therein, a jaw adapted to freely slide on said bar, said lower jaw having in line with the shank-cavity in its lower front portion a circular plug having a flattened side surface containing a series of teeth, and also provided in the upper rear portion of its shank-cavity with a series of teeth contained on the upper end face of a downward and rearward inclined circular plug.

4. In a wrench, the combination of a sliding jaw having on its lower front portion a plug with a flattened roughened surface in line with the shank-cavity therein, a flat spring secured to the side of the movable jaw, a movable pin mounted in a hole through the side of said jaw and forced against the wrench-bar by said spring, a circular plug in the upper rear portion of the movable jaw with a roughened end surface also in line with the shank-cavity.

5. In a wrench, the combination with a bar having a fixed jaw, of a sliding jaw thereon with a plug having a roughened flat surface in line with the shank-cavity therein, a friction-pin mounted in said jaw and bearing on the side of the bar, a flat spring secured to the jaw and bearing against the pin to hold it in engagement with the bar, substantially as described.

6. A wrench comprising a bar having a jaw fixed therein, a movable jaw slidably mounted on said bar, a plug secured in said jaw and having a serrated surface to engage the front of the wrench-bar, a circular plug with a serrated face for contact with the rear of the said bar in the upper rear portion of said movable jaw, a spring-actuated pin in the back of said jaw, and a spring-actuated pin in the side of the jaw, both of said pins being arranged to frictionally engage the bar upon which said jaw is mounted.

696,407. JAR-CLOSURE. OLIVER BRIM, Leesville, W. Va. Filed May 21, 1901. Serial No. 61,248. (No model.)

Claim.—1. In a jar-closure a circular cover provided with a multiplicity of angular grooves on its top each consisting of two converging straight depressions that cut said cover into corners of a circle, an annular projection on the lower side of the cover to fit in the neck of the jar, a projecting rim on the exterior of the neck of the jar, and angular metal clamps having their ends bent downward to form hooks, said clamps being adapted to seat in said grooves and engage the lower edge of the rim on the neck of the jar, substantially as shown and described.

2. In a jar-closure, a jar with a projecting rim, an annular shelf on the interior of said rim, a cover having an annular projection on its lower side, a gasket between the upper edge of the rim and the cover, a gasket between said annular shelf and said annular projection, a multiplicity of angular grooves on the upper side of the cover, said grooves extending in converging straight lines from the periphery of the cover toward the center thereof, and clamps to fit in said grooves and engage the bottom of the rim, substantially as shown and described.

696,408. CONVERTIBLE RAILWAY-CAR. JOHN A. BELL, Philadelphia, Pa. Filed Jan. 3, 1901. Serial No. 42,488. (No model.)

Claim.—1. In a convertible car, the combination with panels for closing the sides thereof, the lower or base panel being adapted to receive the upper panel, of means whereby the said lower panel with the upper panel may be stored beneath the roof of the car.

2. In a convertible car having side openings defined by upright posts, means for closing each of said openings comprising an upper and a lower panel, the lower panel being constructed to receive the upper panel when it is desired to open said openings, a roof for said car provided with storage-space and means whereby the said base-panel carrying the upper panel can be bodily lifted into the said storage-space in the roof.

3. In a convertible car having one or more side openings, the combination with upright posts to define said openings, of means for closing said openings comprising panels, one of said panels being constructed to receive and hold another of the panels, a roof for the car having space therein in which to store the panels, and means to permit said respective panels to be lifted bodily into the said space in the roof of the car.

4. In a convertible car having side openings, upright posts to define said openings, a roof for the car provided with storage-space, panels fitting between said posts to close the openings for winter use, each comprising a lower or base panel, and an upper or sub-panel, the lower panel being constructed to receive and hold the upper panel when it is desired to store the same, and means whereby the said base-panel may be bodily lifted and guided into the roof storage-space.

5. In a convertible car having side openings, upright posts to define said openings, a roof for the car provided with storage-space therein, means for closing each of said openings comprising a hollow base-panel and an upper or sub-panel, the said sub-panel being adapted to be placed inside the hollow portion of the base-panel when it is desired to open the side of the car, and means whereby the said base-panel can be bodily lifted into the said roof-space.

6. In a convertible car having side openings therein, upright posts to define said openings, a roof for the car provided with storage-space, means to close said openings including a hollow base-panel forming a box or casing, an upper or sub-panel adapted to slide down inside the box or casing, and means to guide the said box or casing to the space within the roof for the purpose of storage.

7. A convertible car provided with openings therein, upright posts to define said openings, a roof for the car having storage-space formed therein, means to close said openings comprising a base-panel having an inner and an outer wall spaced apart, and an upper or sub-panel adapted to slide down into the space between the said walls when it is desired to open the side of the car, and guiding means connected with said posts whereby the said base-panel with the contained upper panel can be lifted into the roof storage-space.

8. A convertible car provided with side openings therein, upright posts to define said openings, and having grooves formed in the opposing faces or sides of said posts, a roof for the car provided with storage-space corresponding to the said openings in the car sides, means for closing said openings comprising a base-panel having an open space between its sides and transverse or legs guided in one of said grooves, an upper or sub-panel sliding bodily in another of said grooves, and means for guiding said sub-panel down into the receptacle of the base-panel, and further means whereby the said base-panel can be lifted into the said roof storage-space.

9. A convertible car provided with side openings therein, upright posts to define said openings, and having grooves formed in their opposing faces or sides, horns or braces in the top of the car, forming continuations of said posts, one of said grooves or each face being extended into said horn or brace, means for closing said openings consisting of a box or casing

panel guided by said extended groove; and another panel guided by another groove and adapted to be received by said box or casing panel whereby both may be bodily lifted and guided to the top of the car for storage purposes between the horns or braces.

10. A convertible car having side openings, upright posts to define said openings and having grooves in their opposing faces, a roof for the car, horns or braces forming continuations of said posts into the roof, one of said grooves being extended into the horns and notches such as 43 being formed near the outer end of said extended portion of the groove, a hollow base-panel having legs or transverse sliding in said groove, a sub-panel normally held in another of said grooves when the side of the car is closed and adapted to drop into said hollow base-panel, whereby, when the said base-panel with its contained sub-panel is raised, the said legs and grooves will guide the same into the space between the horns or braces in the roof, and one set of legs or transverse can be guided into the said notches 43 to hold the panel in its raised position.

11. In a convertible car having side openings, posts to define said openings, grooves in the opposing faces of said posts, arms or braces in the roof of the car forming continuations of said posts and into which one groove is extended, means to close the opening between said posts comprising a lower panel guided by the extended groove, a sub-panel guided by another of said grooves with its inner side on a line with the outside of the lower panel when the opening is closed, means whereby the sub-panel can be dropped inside the base-panel, and the latter being guided by its grooves can be lifted into the space between the arms or braces.

12. In a convertible car having side openings therein, upright posts to define said openings, and removable sections adapted to be placed in said openings comprising a base-panel and a sub-panel, the base-panel being constructed to receive the sub-panel when it is desired to remove the sections and the sub-panel being constructed to receive the base-panel for storage purposes.

13. In a convertible car having side openings, posts to define said openings and removable sections to close said openings comprising a base-panel and a sub-panel, the base-panel being constructed to receive the sub-panel when it is desired to remove the sections and the sub-panel being made in more than one section to more readily fit the receptacle of the base-panel.

14. In a convertible car having side openings, posts to define said openings, and removable sections to close said openings for winter use, comprising a box-like or hollow base-panel, and an upper sub-panel, the latter being made in hinged sections adapted to fold together and slide down into the box or base-panel for storage purposes.

15. In a convertible car having side openings, upright posts to define said openings, removable sections to close said openings comprising a hollow lower or base-panel having a lid or cover therefor, and an upper or sub-panel adapted to slide down into said base-panel, which when the lid is closed is ready for removal and storage.

16. In a convertible car having side openings, upright posts to define said openings, removable sections to close said openings comprising a lower or base-panel having an inner wall and an outer wall conforming to the desired contour of the outside of the car, said walls being spaced apart by rigid end pieces and a lid hinged to the inner wall to close the box, an upper sub-panel against the lower edge of which the said lid presses when down and the sub-panel is in place, the said lid then serving as the window-sill, and means whereby the said lid may be raised, the sub-panel dropped down inside the box, the lid again closed, and the whole removed for storage purposes.

17. In a convertible car having side openings, upright posts to define said openings, removable sections to close said openings comprising a lower or base-panel having an inner wall and an outer wall conforming to the desired contour of the outside of the car, said walls being spaced apart by rigid end pieces and a lid hinged to the inner wall to close the box, an upper sub-panel composed of sections against the lower edge of which the said lid presses when down, to hold the same in place and to form the window-sill, and means whereby the said lid may be raised, the sub-panel folded up and placed between the walls of the base-panel and the whole removed for storage purposes.

18. In a convertible car having side openings, upright posts to define said openings, the opposing faces of said posts being broken up into longitudinal parts in different places, a base-panel extending between the portions of said posts furthest apart, and a sub-panel between the parts a less distance apart, whereby the sub-panel is narrow enough to be received and held by the base-panel, a guiding means for the base-panel connected with the said posts, and means whereby the said base-panel with its sub-panel may be lifted and stored away.

19. In a convertible car having side openings, posts to define said openings, and having grooves formed in the opposing faces, the bottom of one of said grooves being higher than the faces or edges of another, means to close said openings comprising a base-panel having a receptacle therein and guided by said deeper groove, a sub-panel guided by the other groove, the inner edge of which is removed, for part of its length

to allow the bottom of said sub-panel to swing over the receptacle of the lower panel and to pass down therein, the latter being adapted to be lifted and stored in the roof of the car.

20. In a convertible car having side openings therein, upright posts to define said openings, and having an inner and an outer groove on their opposing faces, a roof for the car provided with storage-space, means to close said openings, comprising a hollow base-panel guided by said inner groove, a sub-panel guided by said outer groove, and located near the outer edge of the post and substantially on a line with the outside of the base-panel, the lower portion of the inner edge of said outer groove being removed so as to permit the lower edge of the sub-panel to swing forward over the hollow base-panel and drop therein, said base-panel being adapted to be lifted and guided by its grooves into the said space in the roof.

21. In a convertible car having side openings therein, upright posts to define said openings, and having an inner and an outer groove on their opposing faces, a roof for the car provided with storage-space, means to close said openings, comprising a hollow base-panel guided by said inner groove, a sub-panel composed of sections and guided by said outer groove, the inner edge of the grooves along the bottom section of the panel being removed to allow it to swing forward over the base-panel and to drop therein, and means whereby the said base-panel can be lifted to the storage-space in the roof.

22. In a convertible car having side openings therein, upright posts to define said openings, and having an inner and an outer groove on their opposing faces, a roof for the car provided with storage-space, means to close said openings, comprising a hollow base-panel guided by said inner groove, a sub-panel composed of sections guided by said outer groove, the inner edge of the groove along the bottom section of the panel being removed to allow it to swing forward over the base-panel and means whereby the said sub-panel may be drawn forward, folded up and dropped into the said hollow panel and roof storage-space.

23. In a convertible car having side openings, upright posts to define said openings, and having grooves formed in the opposing faces of said posts, a roof for the car provided with storage-space therein, means to close said openings comprising a box base-panel having a lid and an upper sectional sub-panel adapted to fold up and slide snugly into the base-panel, the latter being adapted to be guided in one set of said grooves to the roof storage-space.

24. In a convertible car having side openings therein, upright posts to define said openings, and having grooves in their opposing faces, means to close said openings comprising a base-panel slidable in one set of grooves, and a sub-panel slidable in another set of grooves, and a certain having a rod also slidable in one of said sets of grooves.

25. In a convertible car having side openings therein, upright posts to define said openings, and having grooves formed in the opposing faces, means to close said openings comprising a base-panel slidable in one of said grooves and a sub-panel slidable in another set of grooves, and a certain having a rod slidable in the base-panel grooves.

26. In a convertible car having side openings, upright posts to define said openings having grooves formed in their opposing faces, a roof for the car having space formed therein, means to close said openings comprising a base-panel adapted to slide in the inner groove, a sub-panel adapted to slide in the outer groove, the base-panel being constructed to be lifted into the storage-space in the roof, and a certain having a rod which is capable of sliding in the base-panel grooves whether the said panel is in position between the lower ends of the posts or stored in the top of the car.

27. In a convertible car having side openings, upright posts to define said openings, a roof having storage-space therein, means to close said openings, comprising a base-panel, adapted to be lifted and stored in said roof-space, and a sub-panel, a guiding means for the base-panel connected with said posts, a curtain adapted to be guided by the same means, and additional means for moving said curtain out of the way of the base-panel when it is lifted up or down.

28. In a car, the combination with the posts, a head-lining forming the inside of a roof-pocket above the posts, said lining comprising a panel hinged at the upper inner end of the pocket, and means for securing the lower free end of the panel to the lower end of the pocket, substantially as described.

29. In a car, upright side posts, a curtain-roll, a hinged head-lining adapted to open and expose the roll, and a guiding means for said curtain connected with said posts.

30. In a car, upright side posts having grooves in their opposing faces, a curtain guided by said grooves, and roll on which said curtain is wound, a hinged or pivoted support for said roll whereby the same may be entirely removed from the grooves or the path of anything moving therein.

31. In a car, upright side posts having grooves in their opposing faces, a curtain guided by said grooves, a roll for said curtain in the top

of the car, a support of said roll hinged at its inner end and allowing the said roll to be swung inward away from the upper ends of the grooves for purposes of inspection, and whereby the curtain is entirely removed from the grooves.

32. In a convertible car having side openings, posts to define said openings extending up into the roof of the car and having grooves in their opposing faces, means to close said openings comprising a base-panel and a mesh-panel, the said base-panel being constructed to receive the said mesh-panel and to be guided by said grooves into the top of the car, and a hinged head-lining adapted to be swung aside to permit a free passage for the said panel from the upright portions of said posts to the roof portions and vice versa.

33. In a convertible car having side openings, posts to define said openings, a roof provided with spaces therein, means to close said openings comprising a base-panel and a mesh-panel adapted to be stored in the roof-spaces, and a removable head-lining corresponding to said space to readily permit said storage operation.

34. In a convertible car having openings in its sides, posts to define said openings, braces or horns in the roof of the car forming continuations of the posts and having grooves in their opposing faces corresponding to similar grooves in the posts, means to close said openings comprising a base-panel and a mesh-panel, the base-panel being constructed to receive the mesh-panel and having legs near the top and bottom fitting in said grooves to guide the same into the space in the roof between the said horns for storage purposes, and a head-lining extending inward from the posts hinged near its inner end so that it may swing away from the posts to provide room for the panel to pass from the posts to the roof-spaces.

35. In a convertible car having openings in its sides, posts to define said openings, braces or horns in the roof of the car forming continuations of the posts and having grooves in their opposing faces corresponding to similar grooves in the posts, means to close said openings comprising a base-panel and a mesh-panel, the base-panel being constructed to receive the mesh-panel and having legs near the top and bottom fitting in said grooves to guide the same into the space in the roof between the said horns for storage purposes, and a head-lining panel adjacent the posts, hinged at its inner end, and a curtain-roll carried by said head-lining and journaled near its outer end, so that both the head-lining panel and the roll may be swung away from the posts.

36. In a car, the combination of a swinging roof-section, a curtain carried thereby, side posts for the car having grooves, the free end of the said curtain being guided by said grooves.

37. In a car, the combination of a swinging roof-section having a recess formed therein, a curtain carried on the section in said recess, side posts for the car having grooves for the free end of the curtain and aligning with the said recess, when the said swinging section is in normal position.

38. The combination in a convertible car, having side openings and a roof storage-space, of means for closing said openings comprising a base-panel and a mesh-panel, and means for dropping the mesh-panel into the base-panel, the said base-panel being adapted to be lifted into the roof storage-space.

39. In a car, the combination with posts to define side openings, removable panels to close said openings comprising a lower panel and an upper panel, the upper panel being adapted to be stored in the lower panel and readily raised therefrom, whereby the car may be used as an open or semi-open car.

40. In a street-car having side openings, the combination with posts to define said openings, removable panels to close said openings comprising a lower panel having a pocket, and an upper mesh-panel to be stored in said pocket, and to be readily raised therefrom when the car is being used as a semi-open car.

41. In a street-car having side openings, posts to define said openings, means to close the openings comprising a lower or base panel having a pocket and adapted to remain in position when the car is closed or semi-open, and an upper mesh-panel adapted to be stored in said pocket for either semi-open or open use of the car.

42. In a street-car having side openings, posts to define the same, removable panels to close the openings comprising a lower panel having a pocket and an upper panel adapted to be stored in said pocket either for bodily removing or for semi-open use of the car, and a curtain capable of use during the closed, semi-open, or open conditions of the car.

43. In a car, the combination with removable panels to close side openings comprising a lower panel and an upper panel, both panels being removed for open-car use, and only the upper panel for semi-open use, and a curtain capable of being drawn only to the top of the lower panel in the closed or semi-open conditions of the car, and to the floor in its open condition.

44. In a convertible car having side openings and roof storage-spaces, side posts to define said openings, panels to close said openings and adapted

to be stored in the roof, the lower end of the stored panel resting against an abutment in said space.

45. In a convertible car having side openings and roof storage-spaces, side posts to define said openings, means to close said openings comprising a base-panel and a mesh-panel, means for lifting and storing said panels in the said space, and an abutment in said space for the lower end of the stored panel.

46. In a car, having side openings, a top having a storage-space therein between the roof and the ceiling and the weather-board, removable panels for said side openings adapted to be stored in said space comprising an upper and a lower panel and an abutment for said lower panel formed in said weather-board.

47. In a car having side openings, a roof provided with a storage-space therein, means to close said openings comprising removable panels adapted to be stored in said roof-space, means to extend and contract the entrance and exit of said space.

48. In a car having side openings, a roof having a storage-space therein, panels to close said openings and adapted to be stored in said space, and a removable part of one wall of said space to allow said panels to pass therein.

49. In a car having side openings, posts to define the openings, a roof provided with a storage-space having an entrance and exit, panels to close said openings and adapted to be stored in the said space, and means to extend said entrance and exit to allow the passage of said panels therethrough.

50. In a car having side openings, a roof having storage-spaces with which said side openings connect, posts to define said openings, panels therethrough adapted to be stored in said spaces, a swinging door or section in the roof to enlarge the entrance to said space to allow the said panels to pass therethrough.

51. A car, provided with spaces in the top thereof and with side panels consisting of mesh-casings and cashes, said casings being adapted to receive said cashes and to be raised into the space in the top of the car, and devices for holding said casings in said spaces, substantially as shown and described.

52. A car which is adapted for use either as an open or a closed car, said car being provided with side panels composed of mesh-casings and cashes, said casings being adapted to receive said cashes, and said casings being adapted to be raised and stored in the top of the car, substantially as shown and described.

53. A car constructed as herein described and provided with spaces in the top thereof, side posts, side panels consisting of window-cashes and mesh-casings, the mesh-casings being adapted to receive the cashes, said side panels being held in place by grooves or by clamps or strips secured to said posts, substantially as shown and described.

54. A car provided with side posts and grooves in the sides thereof, forming spaces to receive side panels, and side panels mounted in said spaces, and consisting of mesh-casings and cashes, said casings being adapted to receive said cashes, substantially as shown and described.

55. A car which is adapted for use either as an open or closed car, and which is provided with vertical side posts which are provided with grooves forming panel-spaces, mesh-casings and cashes mounted in said spaces, said casings being provided with chambers open at the top, and adapted to receive said cashes, said casings being adapted to be raised into spaces in the top of the car and supported therein, substantially as shown and described.

56. A car provided with vertically-movable side panels consisting of mesh-casings and cashes, said casings being adapted to receive said cashes, and spaces in the top of the car into which said casings are adapted to be raised, said spaces being provided with means for holding the said casings in place, substantially as shown and described.

57. A car constructed as herein described and provided with spaces in the top thereof, side panels consisting of window-cashes and mesh-casings, the casings being adapted to receive the cashes, said side panels being held in place by grooves, substantially as shown and described.

58. A car constructed as herein described, and provided with side posts, having grooves in the sides of the said posts, mesh-casings and cashes mounted in the spaces formed by said grooves, said mesh-casings being adapted to receive said cashes, said car also being provided in the top thereof with spaces into which the mesh-casings are adapted to be raised and with devices for holding said mesh-casings in said spaces, substantially as shown and described.

59. In a convertible railway-car, the combination with a car-body having between the roof and ceiling a chamber with a stationary outer wall, and a bottom opening provided for said chamber, of side posts provided with separate mesh and panel grooves communicating with said opening, a mesh and panel guided into and out of said opening by said grooved side posts, and movable into and out of said chamber through said bottom opening, and a movable floor for said opening.

60. In a convertible car, the combination in a car-body having upright

posts, and between the roof and ceiling a chamber with a stationary outer side wall and a bottom opening aligning with the posts, of grooves formed in the posts aligning with the opening, cashes or panels movable in the grooves into and out of said chamber through said bottom opening, and a head-lining hinged at or near the car-ventilator rail, and extending between its hinge and groove in the posts, its lower free end being adapted to enlarge or contract the said chamber within a zone continuous with the height of said cashes or panels, substantially as described.

61. In a convertible car, the combination with the car-body having between the roof and ceiling a chamber with a bottom opening, of a mesh and panel movable into and out of said chamber through said opening, means for supporting the lower end of the lowered mesh, a movable door for said opening, and means to support the upper end of the lowered mesh, substantially as described.

62. In a convertible car, the combination with the car-body having between the roof and ceiling a chamber with a bottom opening of a mesh and panel movable into and out of said chamber through said opening, a movable door for said opening, means to support and guide the mesh and panel as the same are moved into and out of said chamber, substantially as described.

63. In a convertible car, the combination with the car-body, having between the roof and ceiling a chamber with the bottom opening, and posts, of cashes or panels movable along the posts into and out of said chamber through said opening, a movable door for said opening, a curtain, and supports for said curtain mounted on the lower inside end of said door, and grooves for the free end of the curtain formed in the post aligning with the said opening, and adapted to receive said free end.

64. In a convertible car, the combination with a roof, floor, and a ceiling constructed with a panel-receiving chamber having a fixed outer wall, a bottom opening for said chamber formed by an aperture in the ceiling adjacent to said outer wall, of stationary vertical side ribs or posts provided with grooves or panels slidably leading to said chamber-opening, a panel movable in said slideways into and out of said chamber, means for supporting the panel in said chamber, and a door constructed in length with the said panel attached to the ceiling and movable across said opening, substantially as described.

698,409. CONVERTIBLE RAILWAY-CAR. JOHN A. BELL, Philadelphia, Pa. Filed June 2, 1901. Serial No. 62,818. (No Model.)

Claim.—1. In a convertible car having roof-spaces, the combination with the parts having separate grooves each extending into said roof-spaces, of the sliding window cash and panel movable in said grooves, one of said parts being formed with an abutment to support the cash upon the panel, and for moving the cash upward in the grooves as they are raised, and means for separating and supporting the cash and panel in the roof-spaces.

2. In a convertible car, the combination with the parts having separate grooves, the grooved roof-spaces, the sliding window cash and panel, one of said parts being formed with an abutment for the other to bear against, and for sustaining one part from the other when they are raised, the grooves diverging into different horizontal planes in the roof-spaces, whereby means are provided for supporting the mesh and panel in the said space separate from each other.

3. In a convertible open and closed car, the combination of the sliding panel and window-cash, one of said parts being formed with a lateral abutment having a longitudinal recess to receive a portion of the other, so that one vertically supports the other and that the parts may be moved together and one be supported from the other during such movement.

4. In a convertible open and closed car, the combination of the sliding side-closing elements comprising a window-cash and panel with members formed with separate ways or grooves to separately guide said elements when sliding, projections extending from one of said elements into one of the grooves, the other element being guided by said grooves, and members provided with continuations of said grooves located between the ceiling and the roof of the car to receive said projections and elements for guiding them into and out of said space.

5. In a convertible car having side openings, posts to define said openings, separate grooves in each of the opposing faces of said posts, slidable upper and lower panels separately guided by said grooves, and an abutment carried upon the lower end of the upper panel for lifting one by the other when one is lifted.

6. In a convertible car having side openings, posts to define said openings, separate guiding-grooves in each of the opposing faces of said posts, panels to fill said openings and which are separately guided by said grooves, the upper panel having an abutment carried upon its lower edge and projecting over and adapted to rest on top of the other panel.

7. In a convertible car having side openings, upright posts to define said openings and having separate grooves in each of their opposing faces, a panel and a window-cash to close said openings, the window-cash having an abutment upon its lower edge provided with a means to fit over the top of the panel, and means for storing both panel and cash separate from each other in the roof of the car.

8. In a convertible car having openings in its sides, upright posts to define said openings and having separate grooves in each of their opposing faces, a flexible base-panel and a rigid window-cash separately slidable in said grooves, and means carried upon the lower end of said cash for lifting said cash by raising the base-panel and for storing them in the roof of the car.

9. In a convertible car having openings in its sides, roof-spaces, upright posts to define said openings and having continuations extending into said spaces, separate grooves formed on each of the opposing faces of said posts and continuations and thereon diverging into different horizontal planes, the outer of which is higher, a flexible panel movable in the inner of the grooves, a window-cash comprising rigid sections hinged together movable in the outer grooves, and an abutment carried upon the lower end of said cash, said abutment projecting across the path of said flexible panel.

10. In a convertible car having side openings, vertical posts to define said openings and having guides in grooves in their opposing faces, a flexible base-panel, and a sectional mesh-panel guided by said grooves, the upper section of the latter remaining in the grooves when stored, but the lower section being swung inward, until its lower end enters the storage-chamber and lies close to the inner end thereof, an abutment carried upon the lower end of said cash, and the flexible panel lying in its groove beneath the said lower section adapted to rest upon said abutment, whereby they mutually prevent tilting.

698,410. PROCESS OF HARDENING PLASTER-OF-PARIS. ARTHUR BROWNE, Montreal, Canada. Filed Oct. 11, 1900. Serial No. 58,005. (No specimens.)

Claim.—1. The process of hardening plaster-of-paris which consists in subjecting the same to boiling steam maintained in a seething state during treatment, as and for the purposes described.

2. The process of hardening plaster-of-paris which consists in immersing the same in a bath of boiling steam, and in adding to the latter, from time to time, a suitable liquid which maintains the steam-bath in a state of liquefaction and compensates for the loss of the water of evaporation which is driven off by boiling the steam, as set forth.

3. The process of hardening plaster-of-paris articles which consists, first, in preparing an indurating solution by mixing diluted acid with steam and reducing the latter to a liquid condition by the action of heat; then immersing the article in the boiling steam for a proper length of time to thoroughly impregnate the same, and adding acid diluted with a heated condition to the solution from time to time, as set forth.

4. As a new article of manufacture, a desiccated and indurated plaster.

ter-of-pore article impregnated with alum during boiling thereof and having water-color lacquer applied thereto previous to impregnating said article with the alum, as set forth.

5. The process of hardening plaster-of-paris which consists in boiling the same in a soething alum-bath maintained in a state of ebullition by the external application of heat, whereby the plaster-of-paris is saturated through and through all portions thereof by the hardening agent, as set forth.

6. The process herein described of hardening plaster-of-paris which consists in driving off the water of crystallization present in the article by immersing the same in a bath of boiling alum maintained in a soething state during treatment for a sufficient length of time to obtain the desired end, and replacing each water of crystallization by melted alum which, as the hardening agent, impregnates the article through and through the same, as set forth.

7. The process herein described, of hardening articles of plaster which consists in impregnating the article with melted or liquid alum by immersing said article, for a proper length of time, in a bath of melted alum maintained throughout the operation in a boiling condition by the continuous application of heat, and adding to the boiling alum-bath, from time to time, a substance which compensates for the loss by evaporation and maintains each bath in a proper state of liquidation, as set forth.

696,411. COMBINED LATCH AND BOLT. HARRY CHESHER, Philadelphia, Pa. Filed Feb. 26, 1901. Serial No. 48,868. (No model.)

Claim.—1. In a combined latch and bolt, the combination of a latch-bar carried by the door, a keeper secured to the door-frame comprising a hook adapted to be engaged by the latch and a slot adjacent to said hook in line with the latch-bar adapted to receive the said latch-bar when the same is adjusted longitudinally, a bracket carried by the door adapted to support the rear end of the latch-bar, a detent secured to the end of the latch-bar, a longitudinal slot formed in the bracket through which the detent passes and means for engaging the detent at each end of the longitudinal slot, substantially as described.

2. In a combined latch and bolt the combination of a latch-bar to be carried by the door, a keeper adapted to the door-frame comprising a hook for engagement with the latch and a slot adjacent to said hook in said keeper in line with the latch-bar adapted to receive the said latch-bar when the same is adjusted longitudinally, a bracket carried by the door having a recess formed therein of slightly greater height than the width of that portion of the latch-bar adapted to be engaged therein to allow that end of the latch-bar to slide and to have a slight up-and-down movement therein, a longitudinal slot formed through the outer face of the said bracket, a pivoted detent secured to the end of the latch-bar passing through said longitudinal slot and transverse slots formed at each end of the said longitudinal slot, substantially as described.

3. The combination of a combined latch and keeper carried by the door-frame, a longitudinally-adjustable latch-bar supported by the door, a keeper for supporting the rear end of the latch-bar having a horizontally-disposed slot, 11, provided therein, transversely-disposed slots, 12, formed at each of the horizontal slots, a small detent or lever, 10, pivoted loosely to the end of the latch-bar, said lever extending through the slot in the keeper, and a weighted end formed on said lever adapted to cause the same to drop by gravity into one of the transverse slots, and hold the latch-bar in its adjusted position, substantially as described.

696,412. HAIR-DRYING DEVICE. WILLIAM W. COWLEY, Cleveland, Ohio. Filed Jan. 28, 1901. Serial No. 44,978. (No model.)

Claim.—1. A hair-drying device comprising parallel fur-shaped metal lines having substantially-parallel sides and a supporting-handle in line therewith, as and for the purpose specified.

2. A hair-drying device comprising parallel lines formed of wire bent in parallel-sided bands and having both ends inserted in a handle longitudinally aligned therewith, substantially as described.

3. A hair-drying device comprising substantially parallel lines formed of wire bent in bands whose sides are substantially but substantially parallel in general direction and having a handle aligned with the lines, substantially as described.

4. A hair-drying device comprising substantially parallel round-ended lines formed of a single wire bent in substantially parallel-sided bands and having both ends inserted in a handle longitudinally aligned therewith, substantially as shown and described.

696,413. HAMMOCK-SLING. JOHN R. DALEY, New York, N. Y. Filed Mar. 8, 1901. Serial No. 48,890. (No model.)

Claim.—1. As a new article of manufacture a yielding hammock-sling, comprising attached sliding members, with an interposed spring, and a movable rope-hitch member carried by one of said sliding members and movable relative thereto.

2. As a new article of manufacture a yielding hammock-sling, comprising attached sliding members, with an interposed spring and a sliding rope-hitch member at one end.

3. As a new article of manufacture a yielding hammock-sling, comprising attached sliding members with an interposed spring, a sliding rope-hitch member at one end of said sling, and a stop therefor.

4. As a new article of manufacture a yielding hammock-sling, comprising a plurality of members arranged to slide one relatively to and in guides on another, yielding means normally separating said sliding members, a movable rope-hitch at one end of said sling, said rope-hitch being carried by one of said members and movable relative thereto and a hammock-support at the opposite end of said sling, and contained by the other of said members.

5. As a new article of manufacture a yielding hammock-sling, comprising a plurality of members, one supporting another through the medium of a spring, a stop-member carried by one member and adapted to engage another member, a movable rope-hitch member at one end of said sling, said rope-hitch being carried by one of said members and movable relative thereto and a hammock-support at the opposite end of said sling, and contained by the other of said members.

6. As a new article of manufacture a yielding hammock-sling comprising a yoke-like member, a hammock-supporting member sliding within the same, a spring separating said members, and a rope-hitch member arranged to slide in said yoke-like member.

7. As a new article of manufacture a yielding hammock-sling comprising a yoke-like member, a hammock-supporting member sliding within the same, a spring separating said members, and a rope-hitch member arranged to slide in said yoke-like member, said hitch member and yoke member cooperating to hold a rope.

8. As a new article of manufacture a yielding hammock-sling comprising a yoke-like member, a hammock-supporting member sliding within the same, a spring separating said members, a rope-hitch member arranged to slide in said yoke-like member, and a stop to limit the movement of said hitch and yoke members one toward the other.

9. A hammock-sling, provided with a movable rope-hitch member, and a stop to limit the clamping movement of said member, independently of the rope.

10. A hammock-sling having a yoke and a rope-hitch member arranged to slide therein, and provided with a stop to limit its movement, independently of the rope.

11. As a new article of manufacture a hammock-sling containing a carrying member, a hook supported thereby through the medium of a spring, and a rope-hitch member movably mounted on said carrying member, whereby a contained weight is transmitted through said spring to said rope-hitch member to cause the latter to move relative to said carrying member to cooperate with the latter in holding the rope.

12. As a new article of manufacture a hammock-supporting member provided with a head, a rope-supported member having a head, a yoke on one having sliding engagement with the other of said heads, an interposed spring and a sliding rope-hitch member in the end of said yoke.

696,414. PLANE. GEORGE P. DAVIDSON, Port Chester, N. Y. Filed Oct. 28, 1901. Serial No. 50,022. (No model.)

Claim.—1. A plane having, in combination with a plane-iron, a metal support therefor in direct contact with the iron adjacent to its cutting edge; a wooden support also in direct contact with the plane-iron above and on the same side of the iron as the said metal support; a metal reaction member on the opposite side of the plane-iron; and a wooden clamping-wedge insertible between and contacting with the opposed surfaces of the said iron and the said reaction member.

2. In a plane, the combination of a plane-iron having a sole comprised of wooden and of metal portions, the metal portion forming a rest for the lower end of the plane-iron; a wooden portion secured to the plane-iron and forming part thereof, and effective to form a support for the central portions of the plane-iron; legs on the metal portion; and a wooden wedge insertible between said legs and plane-iron to hold said iron in place.

3. A plane having, in combination with a plane-iron, a wooden support in direct contact with the plane-iron above the cutting edge thereof; a metal reaction member on the opposite side of the plane-iron; and a wooden clamping-wedge insertible between and contacting with the opposed surfaces of the said iron and the said reaction member.

4. In a plane, the combination with a plane-iron and a metal frame, of a metal support for said iron in direct contact therewith adjacent to its cutting edge; a wooden support also in direct contact with the plane-iron above and on the same side of the iron as the said metal support; a metal reaction member on the opposite side of the plane-iron; and a wooden clamping-wedge insertible between and contacting with the opposed surfaces of the said iron and the said reaction member.

5. In a plane, the combination with a metal frame; a wooden sole; and a plane-iron, of a metal support for said iron extending from the frame and in direct contact with the iron adjacent to its cutting edge; a wooden support also in direct contact with the plane-iron above and on the same side of the iron as the said metal support; a metal reaction member on the opposite side of the plane-iron; and a wooden clamping-wedge insertible between and contacting with the opposed surfaces of the said iron and the said reaction member.

6. In a plane, the combination with a metal frame; a composite sole; and a plane-iron, of a metal support for said iron extending from the frame and in direct contact with the iron adjacent to its cutting edge; a wooden support also in direct contact with the plane-iron above and on the same side of the iron as the said metal support; a metal reaction member on the opposite side of the plane-iron; and a wooden clamping-wedge insertible between and contacting with the opposed surfaces of the said iron and the said reaction member.

7. In a plane, the combination with a metal frame, and a wooden sole, of a wooden handle-supporting block to which said wooden sole is secured and between which the frame is clamped.

8. In a plane, the combination with a chambered metal frame, of a wooden sole comprising strips insertible in the chambers of the frame; and a wooden handle-supporting block to which said wooden sole is secured and between which the frame is clamped.

9. In a plane, the combination with a chambered metal frame, of a plane-iron, a wooden sole comprising strips insertible in the chambers of the frame in front of and at the rear of the said plane-iron, and wooden handle-supporting blocks also located in front of and at the rear of said plane-iron, and to which the wooden sole is secured and between which said sole and the frame is clamped.

10. In a plane, the combination with a wooden sole, of a metal frame in which said wooden sole is insertible and which is provided with a rubbing surface encircling the wooden sole at the side and at the ends of the plane and wooden handle-supporting blocks to which said wooden sole is secured and between which said sole and the frame is clamped.

11. In a plane, the combination with a metal frame and a plane-iron, of a wooden sole insertible in said frame; a metal support for the plane-iron in direct contact therewith adjacent to its cutting edge; a wooden support also in direct contact with the plane-iron above and on the same side of said iron as the said metal support; legs extending from opposite sides of the metal frame and constituting a reaction member located on the side of the plane-iron opposite to which said metal support and wooden support are situated, and a wooden clamping-wedge insertible between and contacting with the opposed surfaces of the said iron and the said legs.

696,415. ADDING AND SUBTRACTING MACHINE. WILLIAM A. DAY, Kearney, Neb. Filed Nov. 10, 1899. Serial No. 698,108. (No model.)

Claim.—1. The combination with a face-plate provided with a main duplex dial, an auxiliary dial, three additional dials adjacent to said auxiliary dial, all of said dials being suitably graduated, a shaft extending through said main dial, a wheel secured to said shaft provided with a plurality of small openings, a shaft-shaft centrally within each of said additional dials, an indicator secured to each of said shaft-shafts, said shaft-shafts being in gear connection, a supporting-pin secured to said main dial, a bar secured to said pin, a crank secured to said bar, said crank being secured to a suitably-supported shaft, said bar working in said wheel provided with said openings, as and for the purpose set forth.

2. The combination with a suitable supporting-housing provided with a main duplex dial, an auxiliary dial, and three additional dials, of the following instrumentalities, to wit: a pivoted indicator working within said main dial provided with a gear-caster, a pinion working in conjunction with said gear-caster, a star-shaped wheel secured to said pinion, the points of said wheel engaging said main indicator-wheel, a pinion extending from said crank, an indicator within each of said additional dials, a pin secured to each of said indicators, each of said pinions having two teeth and ten teeth, an arm extending from the first of said pinions and adapted to engage the pinion of said additional dial adjacent, an operating-arm extending from said intermediate pinion and adapted to actuate the pinion secured to the third dial-indicator, said first-mentioned pin being actuated by said pinion, as and for the purpose set forth.

696,416. SHOWER-BELL. WILLIAM F. DUNHAM, Philadelphia, Pa. Filed June 12, 1901. Serial No. 64,578. (No model.)

Claim.—1. A cushion for a spout-roll of the character depicted consisting of a heavy hub portion having its periphery formed of a multiplicity of longitudinal dovetailed ribs and recesses, and of an outer peripheral portion consisting of a thick ring of flexible or elastic material having

in interior formed of a multiplicity of longitudinal ribs and recesses complementary to those of the hub portion, said parts being pushed into longitudinal engagement one with the other with the dovetailed ribs of each portion engaging the dovetailed recesses of the other portion.

2. A section for a square-roll of the character described consisting of a heavy hub portion having its periphery formed of a multiplicity of longitudinal dovetailed ribs and recesses formed with curved or rounded edges, and of an outer peripheral portion consisting of a thick ring of flexible or elastic material having its interior formed of a multiplicity of longitudinal ribs and recesses complementary to those of the hub portion, said parts being pushed into longitudinal engagement one with the other with the dovetailed ribs of each portion engaging the dovetailed recesses of the other portion.

3. A square-roll of the character described composed of a series of sections arranged side by side and each consisting of a heavy hub portion having its periphery formed of a multiplicity of longitudinal dovetailed ribs and recesses, and of an outer peripheral portion consisting of a thick ring of flexible or elastic material having its interior formed of a multiplicity of longitudinal ribs and recesses complementary to those of the hub portion, said parts being pushed into longitudinal engagement one with the other with the dovetailed ribs of each portion engaging the dovetailed recesses of the other portion.

4. A square-roll composed of a series of sections arranged side by side and each consisting of an inner portion having its periphery provided with longitudinal ribs and recesses and of an outer peripheral portion having a flexible or elastic surface provided internally with complementary ribs and recesses engaging the ribs and recesses of the inner portion, the ribs of adjacent sections being arranged out of longitudinal alignment.

5. A section for a square-roll of the character described, consisting of a heavy hub portion having its periphery formed of a multiplicity of longitudinal dovetailed ribs and recesses of substantially T-rail shape in cross-section, and of an outer peripheral portion consisting of a thick ring of flexible or elastic material having its interior formed of a multiplicity of longitudinal ribs and recesses complementary to those of the hub portion, said parts being pushed into longitudinal engagement one with the other, with the dovetailed ribs of each portion engaging the dovetailed recesses of the other portion.

696,417. REMOVING AND CHANGING ATTACHMENT FOR NEW-
125 WASHINGTON, ALBERT H. DE VOS, Chicago, Ill. Filed July 11
1900. Serial No. 22,300. (No model.)

Claim.—1. In a sewing-machine attachment, the combination with a suitable supporting-frame, of a hammer carried by an arm pivoted to said frame to swing horizontally thereon and provided with a stop to limit said horizontal movement, a cooperating attachment adapted to direct material into the hammer, and an arm carrying said cooperating attachment, also pivoted to said frame to swing horizontally toward and away from the hammer and a stop to limit the horizontal movement of said latter arm; substantially as described.

2. In a sewing-machine attachment, the combination with a suitable supporting-frame, of an arm longitudinally adjustable with respect thereto and pivoted to swing horizontally thereon, a hammer supported on the end of said arm, a second arm also longitudinally adjustable with respect to said frame and pivoted to swing horizontally thereon, stops for limiting the horizontal oscillation of said arms and a suitable attachment upon the end of the second arm adapted to direct material into the hammer substantially as described.

3. In a sewing-machine attachment, the combination with a suitable frame, of a hammer carried by an arm pivoted to said frame to swing hori-

zontally thereon, an adjustable stop to limit said horizontal movement, a cooperating attachment adapted to direct material into the hammer, an arm carrying said cooperating attachment also pivoted to the frame to swing horizontally toward and away from the hammer and an adjustable stop to limit the horizontal movement of said latter arm; substantially as described.

696,418. APPARATUS FOR GENERATING ACETYLENE GAS
EDWARD H. DUCKENSON, New York, N. Y. Filed June 12, 1897. Serial
No. 640,674. (No model.)

Claim.—1. In a gas-generating apparatus, the combination with a generating-receptacle, of a solid gas-generating reagent rotatably mounted within said receptacle, and means for applying a second reagent upon one side of said solid reagent, and thereby decompose the latter in such manner that it will rotate by gravity and present other parts of its surface to the action of said second reagent, substantially as described.

2. In a gas-generating apparatus, the combination with a receptacle, of a solid reagent rotatably mounted therein, a flexible conduit in communication with a fluid-supply, and a perforated tube supported by and in communication with said conduit and adapted to supply fluid to one side of said solid reagent, and thereby decompose the latter in such manner that it will rotate by gravity and present other parts of its surface to the action of the fluid, substantially as described.

3. In a gas-generating apparatus, the combination with a receptacle, of a solid reagent rotatably mounted therein, means whereby said reagent may be inserted and rotatably mounted in said receptacle, and means for applying a fluid to one side of said solid reagent, and thereby decompose the latter in such manner that it will rotate by gravity and present other parts of its surface to the action of said fluid, substantially as described.

696,419. BOLL-WHEEL OR OTHER INSECT DESTROYER
JOHN A. DRAKE, Fort Worth, and ALEXANDER C. FARRINGTON, Yonkers,
Tex. Filed Sept. 10, 1901. Serial No. 73,608. (No model.)

Claim.—1. An insect-destroyer for killing insects from growing plants comprising one or more pairs of troughs adapted to contain a liquid poison, means for passing the troughs under the plants, and means for agitating the plants as the troughs are passed thereunder consisting of rotary fans for creating constant breeze, means for mounting and operating said fans, and troughs in combination with said fans for striking the plants.

2. An insect-destroyer for killing insects from growing plants comprising one or more pairs of troughs adapted to contain liquid poison, said

ble bows for attaching said troughs in operative position, said bows being high enough to pass above the plants, a screen for each pair of troughs mounted on said bows and extending down even with the top of the walls of each trough for preventing the escape of insects, wheels provided with suitable spindles attached to said troughs for passing said troughs under the plants, a rotary fan for creating a blast mounted above each screen for agitating the plants, and suitable gearing for driving said fans from said wheels.

3. An insect-destroyer comprising one or more pairs of troughs adapted to contain liquid poison, suitable bows for attaching said troughs in operative position, said bows being high enough to pass above the plants, a screen for each pair of troughs mounted on said bows and extending down even with the top of said troughs, wheels provided with suitable spindles attached to said troughs, a rotary fan for creating a blast mounted above each screen and provided with a beveled pinion, a shaft provided with suitable bearings and a beveled cog mounted on said shaft for driving each beveled pinion, a pulley mounted on each shaft, a pulley mounted on one of the spindles of each pair of troughs, and a belt for driving said pulley.

696,420. MECHANICAL STIRRER OR POKER FOR GAS-PRODUCERS
JOHN W. DOUGHERTY, Staunton, Pa. Filed Dec. 1, 1900. Serial
No. 34,348. (No model.)

Claim.—1. In a gas-producer, the combination of a square chamber, a stirrer shaft or shafts extending parallel to walls of said chamber, stirrer-arms on said shaft or shafts, which arms extend substantially to said walls and stir substantially the whole of the horizontal cross-section of said chamber, and means for revolving said shaft or shafts, substantially as described.

2. In a gas-producer, the combination of a chamber having opposite straight walls, a stirrer shaft or shafts extending perpendicular to said walls, stirrer-arms on said shaft or shafts, which arms reach and stir substantially the whole of the horizontal cross-section of said chamber, and means for revolving said shaft or shafts, substantially as described.

3. In a gas-producer, the combination with a horizontal stirrer-shaft having arms thereon, of means for longitudinally reciprocating said shaft, substantially as and for the purpose described.

4. In a gas-producer, the combination with a horizontal stirrer-shaft, of arms on each shaft, means for longitudinally reciprocating said shaft, and means for giving each arm motion about the axis of said shaft, substantially as and for the purpose described.

5. In a gas-producer, the combination with a horizontal stirrer-shaft, of arms on each shaft, means for longitudinally reciprocating said shaft, and means for oscillating each shaft, substantially as and for the purpose described.

6. In a gas-producer, the combination with a stirrer-shaft, of arms thereon, a frame secured in and projecting through a wall of the producer, and a bearing-box for said shaft removably secured in said frame, where-

by said box can be removed to permit the withdrawal of the shaft from the producer, substantially as and for the purpose described.

7. In a gas-producer, the combination with a horizontal stirrer-shaft, of a longitudinal series of teeth on each shaft, and a pinion for engaging said teeth to reciprocate the shaft, substantially as and for the purpose described.

8. In a gas-producer, the combination with a horizontal stirrer-shaft, of a longitudinal series of circular teeth extending around each shaft, a pinion engaging said teeth to reciprocate the shaft, and means for rotating each shaft, substantially as and for the purpose described.

9. In a gas-producer, the combination with a horizontal stirrer-shaft, of a longitudinal series of circular teeth extending around each shaft, a pinion engaging said teeth to reciprocate the shaft, a shaft splined to the stirrer-shaft, a worm on each second shaft, and a worm-wheel engaging said worm, substantially as and for the purpose described.

10. In a gas-producer, the combination of a stirrer-shaft having stirrer-arms thereon, a bearing for said shaft, a box mounted in a wall of the producer, said bearing being removably attached to said box, said box having an opening in line with said bearing, which opening is large enough to permit the passage of said stirrer-arms, and a removable filling in said opening on the fire side of said bearing, substantially as described.

11. In a gas-producer, the combination of a stirrer-shaft having stirrer-arms thereon, a bearing for said shaft, a box mounted in a wall of the producer, said bearing being removably attached to said box, said box having an opening in line with said bearing, which opening is large enough to permit the passage of said stirrer-arms, a removable filling in said opening on the fire side of said bearing, said box having a water-chamber therein, means for conducting water to said chamber, and means for conducting steam therefrom to said producer, substantially as described.

12. The combination of a gas-producer, with one or more poker, and a rock-shaft carrying the same and mounted on the producer so as to be capable of both a rocking and a laterally-reciprocating movement thereon, substantially as specified.

13. The combination of a gas-producer, with one or more hollow poker, a hollow rock-shaft carrying the same and mounted on two producers so as to be capable of both rocking and laterally-reciprocating movement thereon, and means carried by said shaft for supplying water to and discharging it from said poker or pokers, substantially as specified.

14. The combination of a gas-producer, with a rock-shaft extending across the upper part of the same, and mounted in bearings thereon, so as to rock, and a series of pokers projecting downwardly from said rock-shaft, substantially as specified.

696,421. DETACHABLE BOILER-PLUG JULIAN F. DRAKE,
Holly, Minn. Filed Mar. 22, 1901. Serial No. 62,804. (No model.)

Claim.—In a boiler, the combination with a detachable flue, of a nut working with screw-threaded engagement on the outer end of said flue, and the clamping-ring 10 surrounding said flue between said nut and the flue-sheet, which clamping-ring is provided with the annular packing-ring 11 of relatively soft fireproof material, exposed for contact with the flue-sheet and with the part which it directly surrounds, substantially as described.

696,422. CLAMP FOR WASHBOWLS, &c. EDWARD A. DUFFY,
Chicago, Ill. Filed Dec. 20, 1899. Serial No. 741,594. (No model.)

Claim.—1. The combination, with a slab having a cylindrical recess, and a bowl, of a clamping device comprising a longitudinally-split thumb and a clamping-arm integrally connected therewith, a screw threaded to engage the thumb and having a conical or tapering portion to spread the same, and a nut mounted on said screw and bearing against the clamping-arm, substantially as described.

2. The combination, with a slab having a cylindrical recess, and a bowl, of a clamping device comprising a thumb of uniform external diameter adapted to fit the recess and split both longitudinally and trans-

versely, the lower portion being threaded, a screw adapted to fit said threaded portion and having a conical or tapering portion to spread the upper or vertically-split portion of the thimble, a clamping-arm to engage the bowl, and a nut mounted on the screw and bearing against the clamping-arm, substantially as described.

3. The combination, with a slab having a cylindrical recess, and a bowl, of a clamping device comprising a thimble adapted to fit the recess and split both vertically and horizontally, the lower portion being threaded, a clamping-arm adapted to engage the bowl and integrally connected with the thimble, a screw engaging the threaded portion of the thimble and having a tapering or conical portion to spread the thimble, and a nut mounted on said screw and bearing against the clamping-arm, said arm being apertured or dotted for the free passage of the screw, substantially as described.

696,428. PROCESS OF DEVULCANIZING INDIA-RUBBER. GEORGE F. J. DUNN, Brighton, England. Filed Sept. 16, 1901. Serial No. 78,881. (No specimens.)

Claim.—1. In the process of devulcanizing india-rubber the improvement consisting in subjecting the india-rubber, in the presence of water, to the action of an agent containing lime having been heated to redness.

2. In the process of devulcanizing india-rubber the improvement consisting in subjecting the india-rubber, in the presence of water, and with interruption of heat to the action of an agent containing lime having been heated to redness substantially as described.

3. In the process of devulcanizing india-rubber the improvement consisting in subjecting the india-rubber in the presence of water and with intervention of heat to the action of lime having been heated to redness in combination with one or more of the usual adjuncts substantially as described.

4. In the process of devulcanizing india-rubber the improvement consisting in first preparing lime by intense calcination; then sifting the lime and introducing it into water, then kneading the india-rubber, placing it in the solution and boiling, finally removing the india-rubber and washing substantially as described.

696,424. WATER-SUPPLY APPARATUS FOR WATER-CLOSERS. VICTOR J. HENRY, Wollaston, Mass. Filed May 7, 1902. Renewed Jan. 8, 1901. Serial No. 42,948. (No model.)

Claim.—1. A water-supply apparatus comprising a tank having an outlet surrounded by a valve-seat, a hinged valve controlling the outlet, means for opening the valve, a lever fulcrumed to the valve and having a float on its longer arm, and a stop on the valve arranged to cooperate with the lever in causing the lever to close the valve while the water is subsiding in the tank, said stop being adjustable to vary the action of the lever in closing the valve.

2. A water-supply apparatus comprising a tank having an outlet surrounded by a valve-seat, a hinged valve controlling the outlet, means for opening the valve, a lever fulcrumed to the valve and having a float on its longer arm, and a stop on the valve arranged to cooperate with the lever in causing the lever to close the valve while the water is subsiding in the tank, said stop being adjustable to vary the action of the lever in closing the valve.

3. A water-supply apparatus comprising a tank having an outlet surrounded by a valve-seat, a hinged valve controlling the outlet, means for opening the valve, a lever fulcrumed to the valve and having a float on its longer arm, and a stop on the valve arranged to cooperate with the lever in causing the lever to close the valve while the water is subsiding in the tank, said stop being adjustable to vary the action of the lever in closing the valve.

4. A water-supply apparatus comprising a tank having an outlet surrounded by a valve-seat, a hinged valve controlling the outlet, a lever fulcrumed to the valve and having a float on its longer arm and a cam-shaped shorter arm, a stop on the valve arranged to cooperate with the lever in causing the lever to close the valve when the water subsides in the tank, and a fixed stop adjacent to the valve-seat, said cam-shaped arm and fixed stop being arranged relatively to each other and to the lever to arrest the closing movement of the valve before the latter reaches its seat, thereby causing a retarded flow through the outlet until the longer arm of the lever is raised by the rise of water in the tank during said retarded flow, and to then permit the closing of the valve.

5. A water-supply apparatus comprising a tank having an outlet surrounded by a valve-seat, a hinged valve controlling the outlet, a lever fulcrumed to the valve and having a float on its longer arm and a cam-shaped shorter arm, a stop on the valve arranged to cooperate with the lever in causing the lever to close the valve when the water subsides in the tank, and a fixed stop adjacent to the valve-seat, said cam-shaped arm and fixed stop being arranged relatively to each other and to the lever to cooperate as described in first arresting and then permitting the completion of the closing movement of the valve, the said fixed stop being adjustable to vary the period of said retarded flow.

6. A water-supply apparatus comprising a tank having an outlet surrounded by a valve-seat, a hinged valve controlling the outlet, means for opening the valve, a lever fulcrumed to the valve and having a float on its longer arm, a stop on the valve, arranged to limit the independent upward movement of the lever and cause the float thereof to hold the valve open while the float is supported by water in the tank, and a stop on the valve, arranged to limit the independent downward movement of the valve and cause the float to close the valve when the water subsides in the tank.

696,425. LAWNSCAT. MARK C. FARR, Chicago, Ill. Filed July 8, 1901. Serial No. 77,408. (No model.)

Claim.—A resilient lawnscat having a jointed or articulated base and adjustable back, a rack upon the upper side of the base and a pawl attached to the back and adapted to engage with the rack for adjustment, substantially as described.

696,426. FAN. GREEN & FRYMONT, Wash. D.C. Filed May 20, 1901. Serial No. 42,949. (No model.)

Claim.—1. In a fan of the character described, the combination with a base, a bevel-gear centrally mounted upon a vertical shaft within said base, mechanism for operating said shaft, and an arm upon said base, carrying a bracket; of an adjustable socket rotatably mounted in said bracket, a curved arm adjustably mounted in said socket, and a horizontally-disposed fan-shaft supported by said curved arm, carrying a gear adapted to mesh with the gear upon said vertical shaft, substantially as described.

2. In a fan of the character described, the combination with a base, a bevel-gear centrally mounted upon a vertical shaft within said base, mechanism for operating said shaft, and an arm upon said base, carrying a bracket; of an adjustable socket rotatably mounted in said bracket, a curved arm adjustably mounted in said socket, a horizontally-disposed fan-shaft supported by said curved arm, carrying a gear adapted to mesh with the gear upon said vertical shaft, and a centrifugal speed-governor mounted upon said fan-shaft, substantially as described.

3. In a fan, the combination with the base or standard, operating mechanism carried thereby, and an arm carried by said base; of a fan-shaft supported by said arm, mechanism for driving said fan-shaft, mechanism for adjustably securing said fan-shaft in any desired position, and a centrifugal speed-governor carried by said fan-shaft for maintaining a uniform speed of the fan, substantially as described.

4. In a fan, the combination with the base, fan-operating mechanism carried thereby, and a bevel-gear mounted upon a vertical shaft in said base and connected to said fan-operating mechanism; of a fan-shaft carrying a gear-wheel adapted to mesh with the gear-wheel upon said vertical shaft, and a curved arm for adjustably securing said fan-shaft in any desired position in both the horizontal and the vertical planes, without destroying the mesh of the said gears, substantially as described.

5. In a fan, the combination with a base, fan-operating mechanism carried thereby, and a bevel-gear mounted upon a vertical shaft in said base, and connected to said fan-operating mechanism; of a fan-shaft carrying a gear provided with curved teeth adapted to mesh with said bevel-gear upon the vertical shaft, a curved arm having an arc struck with its center in the pitch-line of the two gears, and provided with a bearing for supporting the said fan-shaft, and means for adjusting the inclination of said fan-shaft, substantially as described.

6. In a fan, the combination with a base, fan-operating mechanism carried thereby, and a bevel-gear mounted upon a vertical shaft in said base, and connected to said fan-operating mechanism; of a fan-shaft carrying a gear provided with curved teeth adapted to mesh with said bevel-gear upon the vertical shaft, a curved arm having an arc struck with its center in the pitch-line of the two gears, and provided with a bearing for supporting the said fan-shaft, means for adjusting the inclination of said fan-shaft, and means for adjusting said shaft in the horizontal plane, substantially as described.

7. In a fan, the combination with a base, fan-operating mechanism carried thereby, and a bevel-gear mounted upon a vertical shaft in said base, and connected to said fan-operating mechanism; of a fan-shaft car-

rying a gear provided with curved teeth adapted to mesh with said bevel-gear upon the vertical shaft, a curved arm having an arc struck with its center in the pitch-line of the two gears, and provided with a bearing for supporting the said fan-shaft, means for adjusting the inclination of said fan-shaft, means for adjusting said shaft in the horizontal plane, and a governor upon said fan-shaft for controlling the speed of the fan, substantially as described.

8. In a fan, the combination with a base, a bevel-gear centrally mounted upon a vertical shaft within said base, and mechanism for operating said shaft; of a horizontally-disposed fan-shaft, a gear carried thereby, and an adjustable curved arm supporting said fan-shaft, the curvature of said arm being in an arc of a circle struck from the pitch-line of the two gears, substantially as described.

9. In a fan, the combination with a base, fan-operating mechanism carried thereby, and a bevel-gear mounted in said base; of a fan-shaft carrying a gear-wheel adapted to mesh with the gear-wheel upon said vertical shaft, and a curved arm, adapted to support said fan-shaft in any desired position in both the horizontal and vertical planes, the curve of said arm being in the arc of a circle struck from a pitch-line of the two gears, substantially as described.

696,427. ELECTRIC INDICATING INSTRUMENT. RICHARD FLEMING LYNN, Mass., assignor to General Electric Company, a Corporation of New York. Filed Nov. 21, 1901. Serial No. 42,160. (No model.)

Claim.—1. The combination with a current-indicating device, of means for causing the indications of said device to change with change of wave shape of current by which it is influenced.

2. The combination of an arc-light circuit, means for supplying thereto a substantially constant current, a current-indicating device for said circuit, and means for causing the indications of said device to change with change of wave shape of current in said circuit.

3. The combination of an electric circuit, a magnetic core magnetized to saturation by current flowing in said circuit, a current-indicating device, and means for impressing upon said device an electromotive force which varies in response to variation of magnetization of said core.

4. The combination of an electric circuit, a transformer having its primary in series with said circuit and so proportioned that its magnetic core is magnetized to saturation or near saturation, an indicating device, and connection between the secondary of said transformer and said indicating device.

5. The combination of an electric circuit, a transformer having its primary in series with said circuit, an indicating device connected to the secondary of said transformer, and a device possessing reactance connected in circuit between the said secondary and said indicating device.

6. The combination of an electric circuit arranged to carry in normal operation a substantially constant current, a magnetic core, a winding supplied with current from said circuit and connected on the said core, said core being so proportioned that the difference of potential at the terminals of said winding varies with variation of wave shape of the current in said circuit, and an indicating device operatively related to said winding.

7. The combination with an electric circuit, of a current-indicating device therefor, and means for causing said indicating device to respond not only to changes in the amount of current flowing, but also to changes in the wave shape of the current.

8. The combination with an electric circuit, of a current-indicator therefor, and means for causing said current-indicator to respond not only to changes in the amount of current flowing in said circuit but also to changes of frequency of said current and to changes of wave shape of said current.

690,428. WINDOW. JAMES PRYDE, Briton, England. Filed July 12, 1899. Serial No. 62,000. (No model.)

Claim.—1. In reversible sliding window-sashes pivoted to sash-means for supporting the sash when projecting inwardly or outwardly, consisting of forming the adjacent rabbeted faces of the stile and sash, one with a segmental projection adapted to enter a correspondingly-formed recess in the other, when the sash is swung into a horizontal position and to abut against one wall thereof substantially as set forth.

2. In reversible sliding window-sashes, a sash, a sash pivoted thereto, a segmental projection on one of said parts adapted to enter a correspondingly-formed recess in the other part, a block on one face and a correspondingly-formed recess in the other face, said block together with the segmental projection serving to support the sash, the said block and its recess being independent of the projection and the recess adapted to receive the same, substantially as described.

3. In reversible sliding window-sashes, a sash, a sash pivoted thereto, a segmental projection on one of said parts adapted to enter a correspondingly-formed recess in the other part, a block on one face and a correspondingly-formed recess in the other face, said block together with the segmental projection serving to support the sash, the said block and recess being formed with their meeting edges concentric with the arc of the segmental projection, the said block and its recess being independent of the projection and the recess adapted to receive the same, substantially as described.

696,429. SOLDERING-IRON. HENRY GUNTERMAN and TYRON VAN ALLEN, Schenectady, N. Y., assignors to General Electric Company, a Corporation of New York. Filed Nov. 21, 1900. Serial No. 37,200. (No model.)

Claim.—1. An electric soldering-iron, having its point provided with a shank, and a resistance-coil wound on said shank having its layers separated by a cord of heat-retaining and insulating material.

2. An electric soldering-iron, having its point provided with a shank, said shank projecting radially from said shank near its end, a cord of heat-retaining insulating material wound in a zigzag form on said shank, and a helical coil of bare wire wound transversely to said cord, its layers separated by the strands of said cord.

3. An electric soldering-iron, having its point provided with a shank, radial studs on said shank, a resistance-coil wound helically on said shank, a cord of heat-retaining and insulating material wound lengthwise of the shank around the studs and lying between, and transverse to, adjacent layers of wire, and a jacket inclosing the coil and secured to said studs.

4. In an electric soldering-iron, the combination with a tubular handle, of a perforated tube extending therefrom, a hand secured to the tube, a jacket secured to the hand, a heat-retaining lining for the hand and jacket, a soldering-iron point having a shank, a resistance-coil wound on the shank inside the jacket, with open air-spaces between its turns and layers, and conducting-wires running through the handle and connected with the terminals of the coil.

696,480. PRESS-MOLD FOR HOLLOW ARTICLES. WILLIAM J. GREENWOOD, Trenton, Pa., assignor to Charles L. Finsen, Philadelphia, Pa. Filed July 12, 1901. Serial No. 62,001. (No model.)

Claim.—1. A press-mold for bottles or other hollow articles having a mold-ring centered thereon, a top plate having insulating projections and recesses with the mold-ring, said plate forming a joint with the mold-ring at the top of the bottle, and having a projection entering the mouth of the bottle, and a central hole in said plate for the passage of the plunger for pressing the bottle; substantially as described.

2. A press-mold for bottles or jars, having a mold-ring centered thereon and provided with a globular recess arranged to form a projection at the upper end of the neck, a top plate having insulating projections and recesses with the mold-ring, said plate forming a vertical joint with the mold-ring at the top of the bottle and having a projection entering the mouth of the bottle, the plate also having a central hole for the passage of the plunger for pressing the bottle; substantially as described.

696,481. ENVELOP. WILLIAM A. HARRISON and JAMES C. KARL, Oil City, Pa. Filed July 10, 1901. Serial No. 67,200. (No model.)

Claim.—An envelop comprising a central or body portion, a lower flap, and an upper sealing-flap, wings at the opposite ends of the body portion, a slit cut in the lower flap, the said wings and lower flap being folded to bring the slit over the overlapping edges of the wings, security-flaps carried by the upper edges of the wings and lower flap respectively, the upper flap having a tongue adapted to be passed through the slit and into the space formed between the lower flap and the overlapping ends of the wings, substantially as set forth.

696,482. PRESS FOR BALKING COTTON OR ANALOGOUS MATERIALS. GEORGE E. HARVEY, Hamilton, Canada, and EDWARD A. WEBER, Birmingham, Ala. Filed Mar. 22, 1901. Serial No. 52,687. (No model.)

Claim.—1. In a press, a fixed member having rolls forming its pressure-surface, a vertically-movable member cooperating with said fixed member, a reciprocal table carried by said vertically-movable member and forming the pressure-surface for the same, means for reciprocating said table, means for forming the material to be compressed into a bat, and a folding mechanism carried by said fixed member and means actuated by the movement of said table carried by the vertically-movable member for depositing the bat in layers upon said reciprocal table between the pressure-surfaces of said fixed and movable members.

2. In a press, a fixed member having rolls forming its pressure-surface, a vertically-movable member cooperating with said fixed member and adapted to being tilted, lifts for moving said vertically-movable member and having pivotal connections with the same to permit the tilting, a reciprocal table carried by said vertically-movable member and forming the pressure-surface for the same, means for reciprocating said table, means for forming the material to be compressed into a bat, and a folding mechanism carried by said fixed member and means actuated by the movement of said table carried by the vertically-movable member for depositing the bat in layers upon said table between the pressure-surfaces of said fixed and movable members.

3. In a press, a fixed member having rolls forming its pressure-surface, a vertically-movable member cooperating with said fixed member and adapted to being tilted, lifts for moving said vertically-movable member and having pivotal connections with the same to permit the tilting, a reciprocal table carried by said vertically-movable member and forming the pressure-surface for the same, means for reciprocating said table, means for forming the material to be compressed into a bat, and a folding mechanism carried by said fixed member and means actuated by the movement of said table carried by the vertically-movable member for depositing the bat in layers upon said table between the pressure-surfaces of said fixed and movable members.

then, a vertically-movable member cooperating with said fixed member and adapted to being tilted, lifts for moving said vertically-movable member and having pivotal connections with the same to permit the tilting, a reciprocal table carried by said vertically-movable member and forming the pressure-surface for the same, means for reciprocating said table, a hopper for receiving the material to be compressed, converging endless aprons for conveying the material out of said hopper and forming it into a bat, compressing-rolls for receiving the bat as it leaves the hopper, and a folding mechanism carried by said fixed member and means actuated by the movement of said table carried by the vertically-movable member for depositing the bat in layers upon said table between the pressure-surfaces of said fixed and movable members.

4. In a press, a fixed member having rolls forming its pressure-surface, a vertically-movable member cooperating with said fixed member and adapted to being tilted, cylinders provided with longitudinal internal ribs, pistons pivotedly connected with said movable member and movable in said cylinders and bearing against said ribs, means for introducing fluid under pressure into said cylinders, a reciprocal table carried by said vertically-movable member and forming the pressure-surface for the same, means for reciprocating said table, means for forming the material to be compressed into a bat, and a folding mechanism carried by said fixed member and means actuated by the movement of said table carried by the vertically-movable member for depositing the bat in layers upon said table between the pressure-surfaces of said fixed and movable members.

5. In a press, a base-plate provided with guides, pistons mounted on said base-plate, a fixed member secured to said columns and having rolls forming its pressure-surface, a vertically-movable member cooperating with said fixed member and adapted to being tilted, flanged cylinders coated in said guides, pistons movable in said cylinders and pivotedly connected with said vertically-movable member, means for introducing fluid under pressure into said cylinders, a reciprocal table carried by said vertically-movable member and forming the pressure-surface for the same, means for reciprocating said table, means for forming the material to be compressed into a bat, and a folding mechanism carried by said fixed member and means actuated by the movement of said table carried by the vertically-movable member for depositing the bat in layers upon said table between the pressure-surfaces of said fixed and movable members.

6. In a press, a base-plate provided with guides, columns mounted on said base-plate, a fixed member secured to said columns and having rolls forming its pressure-surface, a vertically-movable member cooperating with said fixed member and adapted to being tilted, brackets pivoted to said movable member, friction-rolls journaled on said brackets and bearing against said columns, flanged cylinders coated in said guides and having longitudinal internal ribs, pistons connected with said movable member and bearing against said ribs and pivotedly connected with said movable member, means for introducing fluid under pressure into said cylinders, a reciprocal table carried by said vertically-movable member and forming the pressure-surface for the same, means for reciprocating said table, means for forming the material to be compressed into a bat, and a folding mechanism carried by said fixed member and means actuated by the movement of said table carried by the vertically-movable member for depositing the bat in layers upon said table between the pressure-surfaces of said fixed and movable members.

7. In a press, relatively movable compressing members, a reciprocal table carried by one of said members, pivoted brackets, folding-rolls carried by said brackets, and a hinged plate connected with said brackets and mounted in the path of travel of said table to be struck by the same and thereby oscillate said brackets.

8. In a press, a fixed member, a movable member cooperating with said fixed member, a reciprocal table carried by said movable member, pivoted brackets, folding-rolls carried by said brackets, and a hinged plate connected with said brackets and mounted in the path of travel of said table to be struck by the same and thereby oscillate said brackets.

9. In a press, relatively movable compressing members, a reciprocal table carried by one of said members, pivoted brackets, folding-rolls carried by said brackets, a hinged plate mounted in the path of travel of said table to be struck by the same, and a rod connecting said plate with said brackets.

10. In a press, relatively movable compressing members, a reciprocal table carried by one of said members, pivoted brackets, folding-rolls carried by said brackets, a hinged plate mounted in the path of travel of said table to be struck by the same, a rod connected with said plate and brackets, and a link connecting said rod with the free end of said plate.

11. In a press, relatively movable compressing members, a reciprocal table carried by one of said members, a pivoted bracket provided with a slotted arm, folding-rolls journaled in said bracket, a rod carrying a pin engaging with the slotted arm of said bracket, a hinged plate mounted in the path of travel of said table to be struck by the same, and a link connecting said rod with the free end of said plate.

12. In a press, relatively movable compressing members, a reciprocal table carried by one of said members, pivoted brackets, relatively adjustable folding-rolls carried by said brackets, a hinged plate mounted in the path of travel of said table to be struck by the same, and a rod connecting said plate with said brackets.

13. In a press, relatively movable compressing members, a reciprocal table carried by one of said members, a pivoted bracket provided with a slotted arm, relatively adjustable bearing-blocks pivoted in said bracket, folding-rolls having their shafts journaled in said bearing-blocks, a hinged plate adapted to be struck by said table, a rod having a pin engaging with the slotted arm of said bracket, and a link connecting said rod with the free end of said plate.

14. In a press, a fixed member, a movable member, means for moving said movable member to and from said fixed member, a reciprocal table carried by said movable member, means for moving said table back and forth on said movable member, an elongated hinged plate extending parallel with the line of movement of said movable member to and from said fixed member and mounted in the path of travel of said table to be struck by the same and thereby oscillate, and a folding mechanism operated by said plate.

15. In a press, a fixed member, a movable member, means for moving said movable member to and from said fixed member, a reciprocal table carried by said movable member, means for moving said table back and forth on said movable member, an elongated hinged plate extending parallel with the line of movement of said movable member to and from said fixed member and mounted in the path of travel of said table to be struck by the same and thereby oscillate, brackets pivoted to said fixed member, folding-rolls carried by said brackets, and means for connecting said plate to said brackets to convey motion from one to the other.

16. In a press, a fixed member, a movable member, means for moving said movable member to and from said fixed member, a reciprocal table carried by said movable member, means for moving said table back and forth on said movable member, an elongated hinged plate extending parallel with the line of movement of said movable member to and from said fixed member and mounted in the path of travel of said table to be struck by the same and thereby oscillate, brackets pivoted to said fixed member, relatively adjustable folding-rolls carried by said brackets, and a rod connecting said plate with said brackets to convey motion from one to the other.

17. In a press, a fixed member, a movable member, means for moving said movable member to and from said fixed member, a reciprocal table carried by said movable member, means for reciprocating said table, brackets pivoted to said fixed member, folding-rolls carried by said brackets, a rod connected with said brackets, and pivoted plates connected with said brackets and mounted in the path of travel of said table to be struck by the same at the end of a stroke and moved thereby to oscillate the brackets carrying the folding-rolls.

18. In a press, a fixed member, a movable member, means for moving the latter to and from said fixed member, a reciprocal table carried by said movable member, means for reciprocating said table back and forth on said movable member, an elongated hinged plate extending parallel with the line of movement of said movable member to and from said fixed member and mounted in the path of travel of said table to be struck by the same and thereby oscillate, and a folding mechanism operated by said plate.

on said movable member, folding mechanism for depositing the material to be compressed in layers between said members, and operative mechanism connected with said folding mechanism and mounted parallel with the line of movement of said movable member to and from the fixed member and in the path of travel of said table to be put in motion by the same.

19. In a press, a fixed member having rolls forming its pressure-surface, a movable member, means for moving the latter to and from said fixed member, a reciprocal table carried by said movable member and forming the pressure-surface for the same, means for reciprocating said table back and forth on said movable member, means for forming the material to be compressed into a bat, a folding mechanism carried by said fixed member for depositing the bat in layers between the pressure-surfaces of the fixed and movable members, and operative mechanism connected with said folding mechanism and mounted parallel with the line of movement of the movable member to and from the fixed member and in the path of travel of said table to be put in motion by the latter.

20. In a press, a fixed member having rolls forming its pressure-surface, a movable member, means for moving the latter to and from said fixed member, a reciprocal table carried by said movable member and forming the pressure-surface for the same, means for reciprocating said table back and forth on said movable member, a hopper for receiving the material to be compressed, conveying rollers upon the material to be compressed, and forming it into a bat, compressing-rolls for receiving the bat as it leaves the hopper, a folding mechanism carried by said fixed member for depositing the bat in layers between the pressure-surfaces of the fixed and movable members, and operative mechanism connected with said folding mechanism and mounted parallel with the line of movement of the movable member to and from the fixed member and in the path of travel of said table to be put in motion by the latter.

21. In a press, a fixed member, a movable member adapted to be tilted, means for moving said movable member to and from said fixed member, a reciprocal table carried by said movable member, means for reciprocating said table back and forth on said movable member, means for forming the material to be compressed into a bat, a folding mechanism carried by said fixed member for depositing the bat in layers between said members, and operative mechanism connected with said folding mechanism and mounted parallel with the line of movement of the movable member to and from the fixed member and in the path of travel of said table to be put in motion by the latter.

22. In a press, a fixed member, a movable member adapted to being tilted, cylinders provided with longitudinal internal ribs, pistons movable in said cylinders and bearing against said ribs and pivotally connected with said movable member, a reciprocal table carried by said movable member, means for reciprocating said table back and forth on said movable member, means for forming the material to be compressed into a bat, a folding mechanism carried by said fixed member for depositing the bat in layers upon said table between the pressure-surfaces of said fixed and movable members, and a hinged plate connected with said folding mechanism and mounted parallel with the line of movement of the movable member to and from the fixed member and in the path of travel of said table to be put in motion by the latter.

23. In a press, a base-plate provided with sockets, columns mounted on said base-plate, a fixed member secured to said columns, a movable member adapted to being tilted, guides carried by said movable member and bearing against said columns, flanged cylinders seated in said sockets and provided with longitudinal internal ribs, pistons movable in said cylinders and bearing against said ribs and pivotally connected with said movable member, a reciprocal table carried by said movable member, means for reciprocating said table back and forth on said movable member, means for forming the material to be compressed into a bat, compressing-rolls for receiving the bat as it leaves the hopper, a folding mechanism for depositing the bat in layers between the pressure-surfaces of the fixed and movable members, and a hinged plate connected with said folding mechanism and mounted parallel with the line of movement of the movable member to and from the fixed member and in the path of travel of said table to be put in motion by the latter.

24. In a press, a fixed member having rolls forming its pressure-surface, a movable member, means for moving the latter to and from said fixed member, a reciprocal table carried by said movable member and forming the pressure-surface for the same, means for reciprocating said table back and forth on said movable member, a hopper for receiving the material to be compressed, conveying rollers upon the material to be compressed, and forming it into a bat, compressing-rolls for receiving the bat as it leaves the hopper, a folding mechanism for depositing the bat in layers between the pressure-surfaces of the fixed and movable members, and a hinged plate connected with said folding mechanism and mounted parallel with the line of movement of the movable member to and from the fixed member and in the path of travel of said table to be put in motion by the latter.

25. In a press, a fixed member, a movable member adapted to being tilted, means for moving said movable member to and from said fixed member, a reciprocal table carried by said movable member, means for reciprocating said table back and forth on said movable member, folding mechanism for depositing the material to be compressed in layers between said members, and a hinged plate connected with said folding mechanism

mounted parallel with the line of movement of said movable member to and from the fixed member and in the path of travel of said table to be struck by the latter and thereby operate said folding mechanism.

26. In a press, a fixed member, a movable member adapted to being tilted, cylinders provided with longitudinal internal ribs, pistons movable in said cylinders and bearing against said ribs and pivotally connected with said movable member, a reciprocal table carried by said movable member, means for reciprocating said table back and forth on said movable member, means for forming the material to be compressed into a bat, a folding mechanism carried by said fixed member for depositing the bat in layers between said members, and a hinged plate connected with said folding mechanism and mounted parallel with the line of movement of the movable member to and from the fixed member and in the path of travel of said table to be struck by the latter and thereby operate said folding mechanism.

27. In a press, a base-plate provided with sockets, columns mounted on said base-plate, a fixed member secured to said columns, a movable member adapted to being tilted, guides carried by said movable member and bearing against said columns, flanged cylinders seated in said sockets and provided with longitudinal internal ribs, pistons movable in said cylinders and bearing against said ribs and pivotally connected with said movable member, a reciprocal table carried by said movable member, means for reciprocating said table back and forth on said movable member, means for forming the material to be compressed into a bat, compressing-rolls for receiving the bat as it leaves the hopper, a folding mechanism for depositing the bat in layers between the pressure-surfaces of the fixed and movable members, and a hinged plate connected with said folding mechanism and mounted parallel with the line of movement of the movable member to and from the fixed member and in the path of travel of said table to be struck by the latter and thereby operate said folding mechanism.

28. In a press, a fixed member having rolls forming its pressure-surface, a vertically-movable member cooperating with said fixed member, a reciprocal table carried by said vertically-movable member and forming the pressure-surface for the same, means for reciprocating said table back and forth on said movable member, a hopper for receiving the material to be compressed, conveying rollers upon the material to be compressed, and forming it into a bat, compressing-rolls for receiving the bat as it leaves the hopper, a folding mechanism carried by said fixed member for depositing the bat in layers upon said table between the pressure-surfaces of said fixed and movable members, and a hinged plate connected with said folding mechanism and mounted parallel with the line of movement of the movable member to and from the fixed member and in the path of travel of said table to be struck by the latter and thereby operate said folding mechanism.

29. In a press, a fixed member having rolls forming its pressure-surface, a vertically-movable member cooperating with said fixed member and adapted to being tilted, lifts for moving said vertically-movable member and having pivotal connections with the same to permit its tilting, a reciprocal table carried by said vertically-movable member and forming the pressure-surface for the same, means for reciprocating said table back and forth on said movable member, means for forming the material to be compressed into a bat, a folding mechanism carried by said fixed member for depositing the bat in layers upon said table between the pressure-surfaces of said fixed and movable members, and a hinged plate connected with said folding mechanism and mounted parallel with the line of movement of the movable member to and from the fixed member and in the path of travel of said table to be struck by the latter and thereby operate said folding mechanism.

30. In a press, a fixed member having rolls forming its pressure-surface, a vertically-movable member cooperating with said fixed member and adapted to being tilted, lifts for moving said vertically-movable member and having pivotal connections with the same to permit its tilting, a reciprocal table carried by said vertically-movable member and forming the pressure-surface for the same, means for reciprocating said table back and forth on said movable member, a hopper for receiving the material to be compressed, conveying rollers upon the material to be compressed, and forming it into a bat, compressing-rolls for receiving the bat as it leaves the hopper, a folding mechanism for depositing the bat in layers upon said table between the pressure-surfaces of said fixed and movable members, and a hinged plate connected with said folding mechanism and mounted parallel with the line of movement of the movable member to and from the fixed member and in the path of travel of said table to be struck by the latter and thereby operate said folding mechanism.

31. In a press, a fixed member having rolls forming its pressure-surface, a vertically-movable member cooperating with said fixed member and adapted to being tilted, cylinders provided with longitudinal internal ribs, pistons pivotally connected with said movable member and movable in said cylinders and bearing against said ribs, means for introducing a fluid under pressure into said cylinders, a reciprocal table carried by said vertically-movable member and forming the pressure-surface for the same, means for reciprocating said table back and forth on said movable member, means for forming the material to be compressed into a bat, a folding mechanism carried by said fixed member for depositing the bat in layers upon said table between the pressure-surfaces of said fixed and

movable members, and a hinged plate connected with said folding mechanism mounted parallel with the line of movement of the movable member to and from the fixed member and in the path of travel of said table to be struck by the latter and thereby operate said folding mechanism.

32. In a press, a base-plate provided with sockets, columns mounted on said base-plate, a fixed member secured to said columns and having rolls forming its pressure-surface, a vertically-movable member cooperating with said fixed member and adapted to being tilted, flanged cylinders seated in said sockets, pistons movable in said cylinders and pivotally connected with said vertically-movable member, means for introducing fluid under pressure into said cylinders, a reciprocal table carried by said vertically-movable member and forming the pressure-surface for the same, means for reciprocating said table back and forth on said movable member, means for forming the material to be compressed into a bat, a folding mechanism carried by said fixed member for depositing the bat in layers upon said table between the pressure-surfaces of said fixed and movable members, and a hinged plate connected with said folding mechanism mounted parallel with the line of movement of said movable member to and from the fixed member and in the path of travel of said table to be struck by the latter and thereby operate said folding mechanism.

33. In a press, a base-plate provided with sockets, columns mounted on said base-plate, a fixed member secured to said columns and having rolls forming its pressure-surface, a vertically-movable member cooperating with said fixed member and adapted to being tilted, brackets secured to said movable member, friction-rolls journaled on said brackets and bearing against said columns, flanged cylinders seated in said sockets and having longitudinal internal ribs, pistons movable in said cylinders and bearing against said ribs and pivotally connected with said movable member, means for introducing fluid under pressure into said cylinders, a reciprocal table carried by said vertically-movable member and forming the pressure-surface for the same, means for reciprocating said table back and forth on said movable member, means for forming the material to be compressed into a bat, a folding mechanism carried by said fixed member for depositing the bat in layers upon said table between the pressure-surfaces of said members, and a hinged plate connected with said folding mechanism mounted parallel with the line of movement of the movable member to and from the fixed member and in the path of travel of said table to be struck by the latter and thereby operate said folding mechanism.

696,483. FISH-BAIT. JAMES HENSON, Doughton, Mich. Filed Jan. 2, 1902. Serial No. 82,851. (No model.)

Claim.—1. In a fish-bait, the combination of a body; a head portion the point of which is above the center of the body portion; a collar between said head and body portion, the upper portion of which projects forwardly and the lower portion of which projects rearwardly, for the purpose specified.

2. In a fish-bait, the combination of a body; a head portion the point of which is above the upper of the body portion whereby spinning is prevented and the bait held right side up; a collar between said head and body portion, for the purpose specified.

3. In a fish-bait, the combination of a body portion; a collar thereon, the upper portion of which projects forwardly, and the lower portion of which projects backwardly, for the purpose specified.

4. In a fish-bait, the combination of a body; having sockets therein; hooks the eyes of which are secured at the bottom of said sockets, for the purpose specified, whereby the hooks are supported to project outwardly from said body.

5. In a fish-bait, the combination of the body portion; hooks detachably secured to said body portion by a screw-eye, the eye of which is open at the outer end of the shank, for the purpose specified.

696,484. SPRING COMPRESSION-COOK. EDWARD S. HEDDER, Newark, N. J. Filed Aug. 15, 1901. Serial No. 71,868. (No model.)

Claim.—1. A compression-cook having the casing *a* with guides *g* for a valve-out, the said movable therein and carrying the valve-washer *j* and having the stem *d* fitted in the guides *g*, the valve-stem *d* having a thread fitted to the valve-out, and having the collar *e* above each thread, the packing-plate *m* fitted to the top of the casing with packing *n* fitted to the under side of the collar, a spring-actuator *f* fitted around the collar, the cover *q* clamping the abutment upon the top of the casing, and the torsional spiral spring *o* wound about the spindle above the abutment, and having its ends secured respectively to the abutment and to the spindle

to normally force the valve-washer upon the seat by the tension of the spring.

2. A compression-cook having a casing with guides for a valve-out, a valve-out movable therein and carrying the valve-washer *j*, a valve-stem having a thread fitted to the valve-out and a collar above each thread, a shoulder in the casing below each collar with a packing-disk and a packing-plate thereon, a recess in the packing-plate with packing fitted to the under side of the collar, a spring-actuator fitted above the collar and provided with marginal flange *f*, the cover *q* screwed upon the top of the casing and adapted to clamp the abutment and packing device, and the spring attached to the abutment and having spring-holder attached to the spindle, whereby the abutment may be adjusted in relation to the spindle and clamped by the cover, substantially as herein set forth.

3. A compression-cook having a casing with guides for a valve-out, a valve-out movable therein and carrying the valve-washer *j*, a valve-stem having a thread fitted to the valve-out and a collar above each thread, a packing-plate fitted to the top of the casing with packing fitted to the collar, an adjustable circular abutment fitted to the top of the collar and a spring-holder secured upon the spindle above the same with a spiral spring having its ends each bent in the plane of the final coil and fixed respectively to sockets in the abutment and in the spring-holder, as and for the purpose set forth.

696,485. GAME APPARATUS. WILLIAM C. HENNINGER, Chicago, Ill. Filed Apr. 25, 1900. Serial No. 12,916. (No model.)

Claim.—1. In a game or puzzle apparatus, the combination with a rectangular box *A*, of a board *a* adapted to form a cover or top for said box and provided at two opposed edges with inwardly-extending flanges *a'* to telescope with the corresponding side portions of the box *A*, the said board having holes therein, thirteen in number, arranged one near each corner of the board and at the corner of a rectangle, one at the center of the rectangle, one between the center and each corner and one between adjacent corner-holes, and a plurality of movable objects, twelve in number, adapted to be stored within the box when not in use but to cooperate with said holes and be manipulated with reference thereto when in use substantially as described, each said object having a line of larger dimensions than said holes whereby the hole is entirely concealed from view when the object is placed thereover, and a shank carried upon the base of each said object to extend through said holes, said shank being tapered to facilitate the seating and removal of the object, substantially as herein described and for the purpose set forth.

2. In a game or puzzle apparatus, the combination with a rectangular box *A*, of a board *a* adapted to form a cover or top for said box and provided at two opposed edges with inwardly-extending flanges *a'* to telescope with the corresponding side portions of the box *A*, the said board having holes therein, thirteen in number, arranged one near each corner of the board and at the corner of a rectangle, one at the center of the rectangle, one between the center and each corner and one between adjacent

corner-holes, and a plurality of movable objects, twelve in number, adapted to be stored within the box when not in use but to cooperate with said holes and be manipulated with reference thereto when in use substantially as described, each said object having a body portion made to simulate a frog and having a base of larger dimensions than said holes where-by the same are completely covered when a frog is placed thereover, a Shank carried upon the base to extend through the holes and being tapered to facilitate seating and removing the object, the shanks and holes being constructed to permit forcing the frogs toward the center of the board, and one of the frogs being provided with a distinguishing-mark such as a different color, substantially as and for the purposes set forth.

696,436. CHANGEABLE SIGN. THEODORE F. HEIDEMANN, Osmersville, Ind., assignor of one-half to Francis T. Kovic, Osmersville, Ind. Filed July 20, 1900. Serial No. 24,494. (No model.)

Claim.—1. In a sign the combination of a frame, sign-sections consisting of plates radiating from a central point journaled side by side therein so that when the flat surface of one set of plates is presented to the eye, the edges of the others are presented, plates upon the upper and lower edges of the radiating plates of each section having studs to fit in between the plates and having a projecting pivot to journal the section in the frame, substantially as shown and described.

2. In a sign the combination of a frame, sign-sections journaled therein each consisting of two sign-bearing plates one having a slot cut into its lower edge upward and the other having a slot cut into its upper edge downward to fit them together, plates having studs to fit in between said sign-bearing plates when they are fitted together and having projecting pivots upon which the sections are journaled in the frame, substantially as shown and described.

696,437. CARDING-ENGINE. JOHN R. HINDLIFF and JAMES HALL, Maynard, Mass. Filed July 1, 1901. Serial No. 66,621. (No model.)

Claim.—1. The combination of a breaker and finisher, each provided with a series of work-rolls, and means arranged to carry back the end of one from the edges of any finishing-roller to the edges of any breaker-roller, substantially as described.

2. The combination of a breaker and a finisher, each provided with a series of work-rolls, and means arranged to carry back the end of one from the edges of the first roller of the finisher to the edges of the last roller of the breaker, substantially as described.

3. The combination of a breaker and a finisher, each provided with a series of work-rolls and means for carrying back the end of one from the edges of any finishing-roller to the edges of any breaker-roller, said means including belts arranged in pairs and running from pulleys located at a considerable height above the breaker and finisher to said breaker and finisher, respectively, substantially as described.

696,438. FIRE-KINDER FOR FIRE-ENGINE. HENRY W. RIVER, Scranton, Pa. Filed Dec. 4, 1901. Serial No. 24,626. (No model.)

Claim.—1. The herein-described fire-kindler for fire-engines comprising a standard, a gas-pipe, a turn-valve supported therein and having connection with said gas-pipe, a gas-supply, an arm extending upward from the turn-valve, a weight adapted to hold the said turn-valve normally closed, and the arm extended upward arranged to be turned over by the fire-box of an engine passing over it, whereby the said turn-valve is operated, substantially as and for the purpose specified.

2. A fire-kindler for fire-engines comprising a gas-pipe, said pipe leading to a valve secured by a standard, and a small passage-way connected with the pipe above and below the valve, a turn-cock arranged to support a flame above the valve, a turn-cock arranged therein, and counterbalanced so as to remain normally closed, and provided with an arm extended upward and arranged to come in contact with the fire-box of an engine when it passes thereover, substantially as and for the purpose specified.

3. In a fire-kindler of the kind described, the combination with a gas-pipe, of a gas-tube, a valve controlling the flow therethrough, and a small tube having communication with the main tube above and below the said valve, whereby a small quantity of gas may escape around the valve, and means for automatically opening the valve when the engine passes thereover, substantially as and for the purpose specified.

4. In a fire-kindler of the kind described, the combination with a main gas-supply pipe leading to a valve member, a standard arranged to support said valve member, a small tube arranged to conduct a flow of gas around the valve in the said valve member, and to be lighted in the vicinity of the mouth or opening of the main supply-pipe, and means for automatically operating the said valve for the purpose of controlling the flow of gas through the main supply-pipe, substantially as and for the purpose specified.

696,439. BURIAL-CASKET. CHARLES H. HINER, Springfield, Ohio, assignor to the Springfield Metallic Casket Company, Springfield, Ohio, a Corporation of Ohio. Filed Aug. 26, 1901. Serial No. 72,264. (No model.)

Claim.—1. A casket having fixed ends and vertically-straight sides, the ends having projections thereon to support the cover flush with the tops of said ends, a cover adapted to rest on said projections, consisting in part of a removable lid and in part of movable pieces hinged to each of the straight sides, in their normal position projecting upwardly and inwardly, sliding under the removable lid and forming additional supports therefor, one of said straight sides being rigid with the end pieces, the other with its movable top piece being hinged so as to turn down and thus expose the side of the casket and form, with the main body of the casket, a seat or couch, as described.

2. In a casket, a main casket-body, formed of the bottom, ends and vertically-straight sides, the bottom, ends, and one side being rigid, cover-supports on each end adapted to allow said ends to project upwardly and stand flush with the top of the cover, the cover proper consisting of a removable lid and two hinged pieces attached to the sides, one of said sides being hinged to the main body and adapted, when the lid is removed, to turn with its hinged top piece to form with the main body, a seat-front, while the other top piece is turned back in imitation of a head-rest, the ends of the casket forming the arms of a seat or couch, as set forth.

3. In a casket, the combination with the base and respective ends of said casket, said ends having projections thereon at the side of said casket, of a hinged side with handle-bars thereon, said side, when in its closed position, fitting between said base and said projections, substantially as specified.

4. In a casket, the combination with the ends, and a hinged side piece extending the full outside length of the casket and having legs thereon adjacent to the lower sides of said ends, of a top piece extending between said casket ends, said top piece having rounded ends for said legs, and shoulders to limit the movement of said top piece, substantially as specified.

696,440. SHOOL-LOCK. THOMAS G. HOLLAND, Philadelphia, Pa. Filed May 22, 1899. Serial No. 714,778. (No model.)

Claim.—1. A shoe-lace comprising a lace proper, and an outer sleeve or casing constituting a protector therefor, said sleeve or casing being shorter than the lace proper and arranged thereon in such manner as to leave the lace ends exposed to form the tie, substantially as described.

2. A shoe-lace comprising a lace proper, and an outer sleeve or casing constituting a protector therefor, said sleeve or casing being shorter than the lace proper and removably placed thereon in such manner as to leave the lace ends exposed to form the tie, substantially as described.

3. A shoe-lace, comprising a lace proper, and a sleeve detachably connected with the lace, the ends of the sleeve being reinforced against unraveling, substantially as described.

696,441. BAG FOR REMEDIAL APPLICATIONS. FRANKLIN C. HOLMAN, Chicago, Ill. Filed Oct. 2, 1901. Serial No. 71,411. (No model.)

Claim.—The combination with a bag, of a cover upon one side of the bag to form between this side and the cover a pocket adapted to hold a remedial application, the cover being provided with a restricted opening through which a portion of the contents of the pocket may protrude for application, while the imperforate portions of the cover serve by en-

gaging the balance of the contents of the pocket to hold the same in place, the said cover being permanently fastened to the bag throughout the major portion of its edge and separably secured to the bag throughout the balance of its edge, substantially as described.

696,442. HARVESTER ATTACHMENT. KENNETH HOPPER, Fenton, Minn. Filed Nov. 7, 1901. Serial No. 21,212. (No model.)

Claim.—In combination with a harvester-platform, an attachment made of metal having a vertically-disposed portion of said attachment fastened to said platform, the top of the attachment being bent at right angles and having the end projecting toward the endless carrier of the harvester, said projecting portion being concave and widening toward its free end, adapted to prevent tangled or other grain catching in the edge of the endless carrier, as set forth.

696,443. ROTARY SWEEPER. JOHN J. HARRIS, Springfield, Ohio. Filed June 12, 1901. Serial No. 65,102. (No model.)

Claim.—1. The combination with the supporting-rolls and their spindles and tilting levers, of a rotary sweeper mounted in said levers, and operating-levers, having an adjusting-handle, to control said tilting levers and limit their movement in one direction only, to adjust the height of said sweeper and leave it free to rise over obstructions, substantially as specified.

2. The combination with the supporting-rolls and their spindles and tilting levers, of a rotary sweeper mounted in one end of said levers, adjusting, operating-levers independent of but adapted to contact with the upper side of the end of said tilting levers opposite said sweeper, to limit the movement of said tilting levers in one direction only, and means to hold the operating-lever in different positions to adjust the height of said sweeper, while leaving it free to rise over obstructions, substantially as specified.

3. The combination with the supporting and driving wheels and their spindles, spur-gears and tilting levers mounted on said spindles, of a shaft journaled in one end of each of said levers, a rotary sweeper and pinions attached to said shaft, said pinions being adapted to mesh with said spur-gears, and an adjustable operating-lever independent of and adapted to engage the other ends of said tilting levers to limit their movement in one direction only, whereby the height of the sweeper is adjusted while leaving it free to rise over obstructions, substantially as specified.

4. The combination with the frame and a flat bar pivoted at its ends in front of said frame, of a receptacle having its back to engage said bar and a laterally-extending lever rigidly attached to said bar to turn said bar and thereby lift and dump said receptacle, substantially as specified.

5. The combination with the frame having a flat bar pivoted at its ends extending across the front of said frame, of a receptacle having its back to engage said bar and a laterally-extending lever rigidly attached to said bar to turn said bar and thereby lift and dump said receptacle, substantially as specified.

696,444. CLAM-SHELL BUCKET AND OPERATING MECHANISM. FRANK R. HOLEY, Cleveland, Ohio. Filed Mar. 22, 1901. Serial No. 22,525. (No model.)

Claim.—1. In a combined clam-shell bucket and operating mechanism therefor, a frame, a power-transmitting mechanism mounted in said frame, a scoop, a shaft mounted near the center line of said frame, a support rotatably suspended from said shaft and having its lower end secured to the front end of said scoop, a second shaft mounted below the first-mentioned shaft and at a greater distance from the center line of the frame than the first-mentioned shaft, a support rotatably suspended from said last-mentioned shaft and secured at its lower end to the rear end of said scoop, and means for operatively connecting the power-transmitting mechanism with said scoop.

2. In a combined clam-shell bucket and operating mechanism therefor, a frame, a power-transmitting mechanism mounted in said frame, two scoops located below said frame and adapted to form a single receptacle, a shaft mounted near the center line of said frame, supports suspended from said shaft and connected at their lower ends with the front ends of the respective scoops, shafts mounted near the sides of said frame below the first-mentioned shafts, supports suspended from said shafts and connected at their lower ends with the rear ends of the respective scoops, and means for connecting the respective scoops with the power-transmitting mechanism.

3. In a combined clam-shell bucket and operating mechanism therefor, a frame, a power-wheel mounted in said frame, means for operating the said wheel, a cam-wheel operatively connected to said power-wheel, and a scoop, one end of said scoop being secured to and rotatably supported at a point on the outer circumference of said cam-wheel, and the other end being movably supported from the said frame.

4. In a combined clam-shell bucket and operating mechanism therefor, a frame, a power-wheel mounted in said frame, means for operating the said wheel, cam-wheels mounted on each side of said power-wheel and operatively connected with the said power-wheel, and two scoops adapted to form a single receptacle, the rear end of each of said scoops being secured to and rotatably supported from one of the said cam-wheels, and the front end of each scoop being movably supported from the said frame.

5. In a combined clam-shell bucket and operating mechanism therefor, a frame, a power-wheel mounted in said frame, means for operating the said wheel, a cam-wheel operatively connected to said power-wheel, and a scoop having one end secured to and rotatably supported at a point on the outer circumference of the said cam-wheel, and having the other end supported by arms rotatably secured in the said frame at a point above the said cam-wheel, substantially as described, and for the purpose set forth.

6. In a combined clam-shell bucket and operating mechanism therefor, a frame, a power-transmitting mechanism mounted in said frame, two cam-wheels, one of said cam-wheels being mounted at each side of said frame and operatively connected with the said power-transmitting mechanism, a scoop located below each cam-wheel and having its rear end suspended from a point on the outer circumference of the adjacent cam-wheel, and its front end supported by arms rotatably secured in the said frame at a point above the said cam-wheel, substantially as described and for the purpose set forth.

7. In a combined clam-shell bucket and operating mechanism therefor, a frame, two scoops supported below said frame and adapted to form

a single receptacle, the front end of each of the said scoops being supported by arms rotatably supported from a common shaft in said framework, the rear end of each scoop being supported from a shaft located in the said framework below the first-mentioned shaft, and not in the same vertical plane therewith, a power-wheel mounted in said framework, and means for operatively connecting the said scoops and the said power-wheel.

8. In a combined clam-shell bucket and operating mechanism therefor, a frame, a shaft rotatably mounted in said frame, a power-wheel rigidly mounted on said shaft, a hoisting-cable secured to said power-wheel, a cable-drum rigidly mounted on the outer end of said shaft, a cam-wheel rotatably mounted in said frame, a cable operatively connecting said cable-drum and said cam-wheel, a shaft mounted in said frame above the said power-wheel, a support rotatably suspended from said shaft, and a scoop secured at its rear end to said cam-wheel and at its front end to the said support, substantially as described, and for the purpose set forth.

9. In a combined clam-shell bucket and operating mechanism therefor, a frame, a power-wheel shaft rotatably mounted in said framework, a power-wheel rigidly mounted on said shaft, a hoisting-cable operatively secured to said power-wheel, a cable-drum rigidly mounted on said power-wheel shaft, cam-wheels rotatably mounted in said framework on each side of said power-wheel shaft, cables connecting the said cable-drum and said cam-wheels, supports rotatably secured in said framework above the said power-wheel shaft on each side thereof and extending down below the bottom of the said framework, and a scoop operatively secured to the respective cam-wheels and the respective supports on each side of the said power-wheel shaft.

696,445. MACHINE FOR MAKING WOODEN BUTTER-DISHES. EDWIN R. TRACE, Brooklyn, N. Y. Filed Jan. 12, 1900. Serial No. 1,901. (No model.)

Claim.—1. A machine for making wooden dishes and the like, comprising a main frame, pivoted levers mounted therein and having their adjacent ends pivotally connected to each other at their ends, means operated by said levers for automatically cutting the blanks and shaping the same, and means for working said levers, substantially as set forth.

2. A machine for making wooden dishes and the like, comprising a main frame, pivoted levers mounted therein and having their adjacent ends pivotally connected to each other at their ends, means operated by said levers for automatically cutting the blanks and shaping the same, a pitman pivotally connected to one of said levers, and a shaft to which said pitman is connected and means for operating the same, substantially as set forth.

3. A machine for making wooden dishes and the like, comprising a main frame, pivoted levers mounted therein and pivotally connected to each other at their ends, means operated by one set of said levers for automatically cutting the blanks, means operated by the other set of said levers for shaping the said blanks, a sleeve pivotally connected to one of said levers, a pitman passed therethrough, means for operating said pitman, and means for limiting the movement of said pitman, substantially as set forth.

4. A machine for making wooden dishes and the like comprising a

main frame, a pair of long levers pivoted to one end of said frame, a pair of shorter levers pivoted to the opposite end of said frame, said levers having their adjacent ends pivotally connected to each other, means operated by said levers for respectively cutting and shaping the blanks, and means for operating said levers, substantially as set forth.

5. A machine for making wooden dishes and the like, comprising a main frame, a pair of long levers pivoted to one end of said frame, means operated thereby for cutting the blanks, a pair of shorter levers pivoted to the opposite end of said frame, and having slots formed therein, pins carried by said former levers and working in said slots, means operated by said shorter levers for shaping the blanks, and means for rocking said levers, substantially as set forth.

6. A machine for making wooden dishes and the like comprising a main frame, a pair of levers pivotally mounted therein, a rod or bar connecting said levers, blank-forming mechanism pivotally supported by said rod or bar, a rock-shaft mounted in said frame, levers keyed thereto and pivotally connected at their ends to said former levers, an arm or member keyed to said rock-shaft, shaping mechanism connected thereto, and means for operating said levers, substantially as set forth.

7. A machine for making wooden dishes and the like, comprising a main frame or table, cutting and scoring knives arranged thereon, a reciprocating blank-forming die coacting with said knives, a pivoted operating-lever therefor, means for operating the latter, a shaper mounted adjacent said die, a pivoted operating-lever therefor said operating-levers having their adjacent ends pivotally connected, means for disengaging the blanks from the knives, and means for automatically transferring the same to said shaper, substantially as set forth.

8. A machine for making wooden dishes and the like, comprising a main frame or table having depending ears, a depending frame secured to said ears, shaping members carried by said depending frame, a reciprocating shaper-die coacting therewith, shaping mechanism also supported in said ears, and means for operating the same, as set forth.

9. A machine for making wooden dishes and the like, comprising a main frame or table having depending ears, a depending frame secured to the latter, shaping members carried by said depending frame, a spring-pressed table or platform carried by said depending frame, a reciprocating shaper-die coacting with said shaping members, shaping mechanism also supported in said ears, and means for operating the same, as set forth.

10. A machine for making wooden dishes and the like, comprising a main frame or table having depending ears, a depending frame secured to the latter, shaping members carried by said depending frame, a vertical rod mounted in said depending frame, a table or platform carried thereby, a coil-spring encircling said rod, a shaper-die coacting with said shaping members and said table, shaping mechanism also supported in said ears, and means for operating the same, as set forth.

11. A machine for making wooden dishes and the like, comprising a main frame or table, a depending frame secured thereto, and provided with diverging heads or enlargements, spring-plates secured to the opposite faces of said heads or enlargements, pivoted plates secured to opposite sides of said depending frame, a shaper-die, and means for operating the same, substantially as set forth.

12. A machine for making wooden dishes and the like, comprising a main frame or table, a depending frame secured thereto and provided with diverging heads or enlargements, diverging plates pivoted to opposite sides of said depending frame and at right angles thereto, means for periodically raising said plates, a shaper-die, and means for operating the same, substantially as set forth.

13. A machine for making wooden dishes and the like, comprising a main frame or table, a depending frame secured thereto and provided with diverging heads or enlargements, plates pivoted to opposite sides of said depending frame and having arms or members projecting therefrom, shafts mounted in said main frame, means for operating the same, cams carried by said shafts designed to engage said arms or members, a shaper-die, and means for operating the same, substantially as set forth.

14. A machine for making wooden dishes and the like, comprising a main frame or table, a depending frame secured thereto and provided with diverging portions, spring-plates secured to said diverging portions, plates pivoted to opposite sides of said depending frame, means for periodically engaging and raising each of said plates, a shaper-die having tapering sides and ends, and means for operating the same, substantially as set forth.

15. A machine for making wooden dishes and the like, comprising a main frame having depending ears, a depending frame secured to said ears and having shaping heads or enlargements, a shaper-die, means for operating the same, sleeves supported in said ears adjacent each of said heads or enlargements, members carried by said sleeves for forming staples, members carried by said sleeves for inserting staples, means for operating said members, and means carried by said shaper-die for clenching said staples, substantially as set forth.

16. A machine for making wooden dishes and the like, comprising a

main frame, a depending frame having shaping heads or enlargements, a shaper-die, means for operating the same, sleeves mounted in said main frame adjacent each of said heads or enlargements, each of said sleeves having a driving-plunger and two bending-plungers, means for alternately operating said bending and said driving plungers, means for feeding wire to said plungers, and means carried by said shaper-die for clenching said staples, substantially as set forth.

17. A machine for making wooden dishes and the like, comprising a main frame, a depending frame having shaping heads or enlargements, a shaper-die, means for operating the same, sleeves mounted in said main frame adjacent each of said heads or enlargements, each of said sleeves having two bending-plungers and a central or driving plunger located therebetween, said plungers having their ends grooved, means for holding a staple in said grooves, and means carried by said shaper-die for clenching the staples, substantially as set forth.

18. A machine for making wooden dishes and the like, comprising a main frame, shaping members carried thereby, a shaper-die, means for operating the same, sleeves mounted in said main frame, each of said sleeves having two bending-plungers and a central driving-plunger located therebetween, said plungers being grooved, means for feeding wire to said grooves, a pivoted member bearing against the grooved end of said driving-plunger, means for operating said plungers, and means carried by said shaper-die for clenching the staples, substantially as set forth.

19. A machine for making wooden dishes and the like, comprising a main frame, shaping members carried thereby, a shaper-die, means for operating the same, sleeves mounted in said main frame, each of said sleeves having two bending-plungers and an intermediate driving-plunger, a spring-pressed lever pivoted to each of said sleeves and having a curved end bearing against the end of said driving-plunger, means for feeding wire to said sleeves, means for operating said plungers, and means carried by said shaper-die for clenching the staples, substantially as set forth.

20. A machine for making wooden dishes and the like, comprising a main frame a depending frame secured thereto, shaping members carried by said depending frame, a shaper-die, means for operating the same, sleeves mounted in said main frame, each of said sleeves having two bending-plungers and an intermediate driving-plunger, means for feeding wire to said sleeves, shafts mounted adjacent said sleeves and having cams keyed thereto designed to engage said plungers, means for operating said shafts, and means carried by said shaper-die for clenching the staples, substantially as set forth.

21. A machine for making wooden dishes and the like, comprising a main frame, shaping members carried thereby, a shaper-die, means for operating the same, sleeves mounted in said main frame, each of said sleeves having two bending-plungers and an intermediate driving-plunger, anti-friction-rollers mounted in the ends of said plungers, shafts mounted in said frame adjacent said sleeves, means for operating the same, cams secured to said shafts designed to periodically engage said bending-plungers, and cams secured to said shafts at a different angle from said former cams and designed to periodically engage said driving-plunger, and means carried by the shaper-die for clenching the staples, substantially as set forth.

22. A machine for making wooden dishes and the like, comprising a main frame, shaping members carried thereby, a shaper-die having slots in its end walls, means for operating said shaper-die, means for forming and driving staples, sliding clenching members carried by said shaper-die and having angular portions projecting through said slots, guides for said clenching members, and means for operating the same, substantially as set forth.

23. A machine for making wooden dishes and the like, comprising a main frame, shaping members carried thereby, a shaper-die, means for operating the same, means for forming and driving staples, sliding clenching members carried by said shaper-die, and provided with angular portions, guides for the latter, depending arms connected to said clenching members, and means for moving said arms, substantially as set forth.

24. A machine for making wooden dishes and the like, comprising a main frame, shaping members carried thereby, a shaper-die, means for operating the same, means for forming and driving a staple, clenching members carried by said shaper-die, springs for holding the same normally separated, U-shaped arms or members connected to said clenching members, and means for moving said U-shaped arms or members, substantially as set forth.

25. A machine for making wooden dishes and the like, comprising a main frame, shaping members carried thereby, a shaper-die, means for operating the same, means for forming and driving a staple, clenching members carried by said shaper-die, depending arms connected thereto, shafts mounted in said main frame, means for operating the same, and cams secured to said shafts and designed to engage said depending arms, substantially as set forth.

26. A machine for making wooden dishes and the like, comprising a main frame, shaping members carried thereby, a shaper-die, means for

operating the same, means for forming and driving staples, sliding clenching members carried by said chaper-die and having angular portions, guides for said clenching members, springs for holding said angular portions normally separated, and means for moving said members as against the action of said springs, substantially as set forth.

27. A machine for making wooden dishes and the like, comprising a main frame, blank forming and shaping mechanism supported thereby, horizontal rods mounted on said main frame, means for reciprocating the same, clamps secured to said rods said clamps each having an angular extension and stationary cans carried by said frame and arranged to alternately engage the front and rear faces of said angular extensions, substantially as and for the purpose set forth.

28. A machine for making wooden dishes and the like, comprising a main frame, blank forming and shaping mechanism supported thereby, horizontal rods mounted on said main frame, means for reciprocating the same, clamps having downwardly-curved stationary jaws secured to said rods, movable jaws pivoted to said stationary jaws and having forward curved lips and rearward upturned vertical portions, and stationary cans arranged to alternately engage the front and rear faces of said upturned portions, substantially as and for the purpose set forth.

29. A machine for making wooden dishes and the like, comprising a main frame, blank forming and shaping mechanism supported thereby, horizontal rods mounted on said main frame, means for reciprocating the same, clamps having stationary jaws provided with chambers, spring-pressed rods working in said chambers, movable jaws pivoted to said stationary jaws and engaged by said spring-pressed rods, said movable jaws having angular portions, and stationary cans arranged to alternately engage the opposite faces of said angular portions, substantially as and for the purpose set forth.

30. A machine for making wooden dishes and the like, comprising a main frame, blank forming and shaping mechanism supported thereby, horizontal rods mounted on said main frame, means for reciprocating the same, clamps having stationary jaws secured to said rods and provided with rear chambers, movable jaws pivoted to said stationary jaws and having lower shoulders, spring-pressed rods working in said chambers and having beveled ends engaging said shoulders, and means for moving said jaws as against the action of said spring-pressed rods, substantially as set forth.

31. A machine for making wooden dishes and the like, comprising a main frame, blank forming and shaping mechanism supported thereby, horizontal rods mounted on said main frame, means for reciprocating the same, clamps having stationary jaws secured to said rods and provided with rear chambers, movable jaws pivoted to said stationary jaws and having lower shoulders and rearward angular portions, spring-pressed rods working in said chambers and having beveled ends engaging said shoulders, and spaced-apart cans arranged to alternately engage the opposite faces of said upturned portions, substantially as and for the purpose set forth.

32. A machine for making wooden dishes and the like, comprising a main frame, blank forming and shaping mechanism supported thereby, horizontal rods mounted on said main frame, means for reciprocating the same, stationary jaws secured to said rods, pivoted jaws carried by said stationary jaws, and having upturned angular portions formed integral therewith, cans designed to engage the front faces of said angular portions, and additional cans designed to engage the rear faces of said angular portions, substantially as set forth.

33. A machine for making wooden dishes and the like, comprising a main frame, blank forming and shaping mechanism supported thereby, horizontal rods mounted on said frame, clamps secured thereto, means for automatically operating said clamps, levers mounted in said frame and provided with toothed segments, a shaft mounted in said frame and carrying segments arranged to intermesh with said former segments, means for operating said shaft, and means for returning said levers to their normal position, substantially as set forth.

34. A machine for making wooden dishes and the like, comprising a main frame, shaping members carried thereby, a chaper-die, means for operating the same, stapling mechanism carried by said frame, a bracket secured to said frame, feeding-drums mounted in said bracket and provided with intermeshing pinions, a lever pivoted to said bracket, a depending weight secured to said lever, a spring-pressed pawl carried by said lever and engaging one of said pinions, a shaft mounted in said frame, means for operating the same, and a cam carried by said shaft designed to periodically engage one end of said lever, substantially as set forth.

696,446. STRAIN-Separator. WILLIAM L. JARVIS, Denver, Colo. Filed Nov. 15, 1902. Renewed Aug. 10, 1904. Serial No. 74,908. (No model.)

Claim.—1. The combination with a tubular boiler of a device for separating steam from the water being heated in the said boiler, said device

comprising a frame having means for reciprocating it, means carried by said frame which are arranged between adjacent tubes of the boiler but out of contact with the tubes, and other means also carried by the frame for circulating the water at the bottom of the boiler and for moving sediment from the bottom of the boiler to the blow-off pipe thereof.

2. The combination with a tubular boiler of a device for separating steam from the water being heated in said boiler, said device comprising a frame having means for reciprocating it longitudinally of the boiler, agitator-blades, carried by said frame and arranged between adjacent tubes but out of contact with said tubes, said agitator-blades being so arranged on said frame relatively to each other as to have their planes of movement overlap.

3. In a device for releasing steam from water, the combination of a frame comprising top, bottom and vertical members, agitator-blades, carried by said frame, and means for reciprocating said frame, substantially as described.

4. In a device for releasing steam from water, the combination of a frame comprising top, bottom and vertical members, agitator-blades, carried by said frame, and means for reciprocating said frame, substantially as described.

5. In combination with a tubular boiler, a frame arranged longitudinally thereof, cross-bars fastened to the tubes of said boiler for supporting said frame, means for reciprocating said frame, and agitator-blades carried by frame and disposed between the tubes of the boiler.

6. In combination with the tubular boiler, a frame arranged longitudinally of the boiler and having means connected therewith for reciprocating it, said frame comprising top, bottom and vertical members detachably secured together, and agitator-blades detachably carried by said frame and disposed between the tubes of the boiler.

7. In combination with a tubular boiler, a frame provided within said boiler and with means for reciprocating it therein, and device carried by said frame which are disposed among the tubes of the boiler and out of contact therewith for stirring and circulating the water in the said boiler.

696,447. ELECTRICAL SWITCH. EDWIN G. KATHMANN, Brooklyn, N. Y., assignor to General Electric Company, a Corporation of New York. Filed June 6, 1901. Serial No. 62,488. (No model.)

Claim.—1. A contact-piece made in the form of a two-armed lever, a finger-lever made to engage one arm of the contact-lever, and a spring

secured to the finger-lever and made to loosely engage the other arm of the contact-lever as to shift the latter as the spring and finger-lever are swung back and forth substantially as described.

2. In an electric switch, the combination with the contacts, of a rocking switch-piece arranged to close the circuit therethrough, a rocking operating-lever, a straight spring fixed to the rocking lever and loosely engaging the switch-piece, and lugs on the switch-piece and rocking lever, which lugs cooperate with each other and with the spring, to normally lock the parts and hold them locked until the movement of the rocking lever has put the spring under sufficient tension to snap the spring into or out of engagement with the switch-contacts.

3. In an electric switch, the combination with switch-contacts, of a rocking switch-piece, a rocking operating-lever, cooperating stops on the switch-piece and operating-lever, and a normally uncoiled straight spring fixed to the operating-lever and loosely engaging an eccentric portion of the switch-piece.

696,448. CHAIR FOR MOTORCYCLE. IRVING W. KENTHLEY, Worcester, Mass. Filed Apr. 4, 1902. Serial No. 678,808. (No model.)

Claim.—1. In a bicycle, the combination of a crank-shaft, a rear wheel, a train of gearing for transmitting power from the crank-shaft to the rear wheel, comprising a crank-shaft gear, a rear-wheel gear, and an intermediate open centered rim-gear having half-receiving flanges upon opposite sides of its working face, a supporting-ring forming an external bearing or box within which the rim-gear is mounted, two sets of bearing-balls for journaling the rim-gear in the supporting-ring, and a retaining-ring secured in place so that it can be adjusted to take up wear on both sets of bearing-balls, substantially as described.

2. In a bicycle, the combination of a crank-shaft, a rear wheel, a train of gearing for transmitting power from the crank-shaft to the rear wheel, comprising a crank-shaft gear 30, a rear-wheel gear 40, an intermediate open-centered rim-gear 55 having half-receiving flanges 56 upon opposite sides of its working face, a supporting-ring 37 forming an external bearing or box within which the rim-gear 55 is supported, two sets of bearing-balls 38, and a retaining-ring 39 having external curved-threads fitting into a threaded socket in the supporting-ring so that the same may be adjusted to take up wear on both sets of bearing-balls, substantially as described.

696,449. INTERCONVERTIBLE COUCH-BED. ALFRED R. KEMMEL, Somerville, Mass. Filed Apr. 1, 1901. Serial No. 68,514. (No model.)

Claim.—1. In an interconvertible couch-bed a suitable longitudinal frame and a horizontal supporting fabric stretched between the end rails of the frame and overhanging the side rails thereof, in combination with horizontally-movable lateral wings adapted to move inwardly beneath the overhanging sides of said fabric, to reinforce it, and outwardly, by a reverse horizontal movement, to form marginal extensions adjoining but disconnected from each side, substantially as set forth.

2. In an interconvertible couch-bed, a central structure having side rails, elevated end rails and a horizontal supporting fabric connected to the ends and overhanging the sides of the frame, in combination with lateral wings having connected longitudinal bars, a series of tapering upright coil-springs secured to each side rail and to said bars, and supporting-brackets connected to the frame and adapted to fluctuate and limit the lateral movement of said wings beneath and beyond said fabric, substantially as set forth.

3. In an interconvertible couch-bed, a suitable frame and its elevated horizontal fabric, and horizontally-movable wings formed with brackets and having a connection of upright coil-springs adapted to move under

the sides of said fabric and to extend their upper surfaces outwardly beyond the margins thereof, in combination with levers projecting from one end of the frame and with push-rods for actuating said wings, substantially as set forth.

4. The described interconvertible couch-bed, comprising a metallic supporting-frame with a yielding horizontal fabric, and horizontally-movable lateral wings, each having parallel angle-iron bars and a double range of tapering coil-springs mounted thereon, in combination with supporting-brackets for each wing, guides and stops to control and limit the movement of said brackets, and suitable actuating-levers, substantially as set forth.

696,450. HORSESHOE. WILLIAM L. KING, Stamford, Iowa. Filed Aug. 12, 1901. Serial No. 71,678. (No model.)

Claim.—A shoe of the character described, provided with enlarged toe and heel portions provided with sockets, composite nails secured in said sockets, inclined seats formed in the upper surface of the respective ends of the shoe directly over the heel-sockets, said seats being deepest at their outer ends, and strips of padding in said seats, substantially as described.

696,451. COLLAPSIBLE BOX. HENRY E. KEMMEL, Stoughton, Mass., assignor of one-third to Melrose Trust, St. Paul, Minn. Filed June 11, 1901. Serial No. 64,102. (No model.)

Claim.—1. A box, comprising a bottom, and pieces having hinge connection therewith, loops on the upper ends of said and pieces, side pieces adapted to engage at their ends in slidesways attached to the end pieces, a top, a hook at one end of said top to engage in one of the loops in an end piece, and a spring-bush at the other end of said top for engaging with the loop of the other end piece the said hook being located below the plane of the cover, substantially as specified.

2. A box, comprising a bottom, and pieces having hinge connection therewith, metal loops on the upper ends of said and pieces, side pieces, a top, a hook on one end of said top for engaging the loop of one of the end pieces, a spring-bush on the other end of said top for engaging with the loop of the other end piece the said hook being arranged below the plane of the top, and loops on the ends of the bottom for receiving said hook and bush, substantially as specified.

3. A box, comprising a bottom, and pieces having hinge connection therewith, side pieces, a top or cover having loops at its side edges to engage against the inner sides of the side pieces, and detaining devices for engaging the top or cover to place the said devices being below the top plane of the cover, substantially as specified.

696,452. AMALGAMATOR. BENNET J. KIM, Fort Wayne, Ind. Filed June 27, 1901. Serial No. 60,186. (No model.)

Claim.—1. An amalgamating apparatus consisting of a retort arranged over a suitable furnace; a rotatable agitator mounted in said retort; means for feeding the ore into the said retort; an inlet-chute adapted to contain a body of mercury to form a seal to prevent the escape of mercury-fumes from the retort and a water seal closing the outlet of said retort, and in which the mercury-fumes of the said retort are condensed and the amalgamated particles of precious metal are collected.

2. In an amalgamating apparatus a cylindrical agitator revolvably mounted in a closed containing-retort; means for heating said retort; a mercury seal arranged in the inlet to the retort; means for feeding the ore through said seal into the agitator; means for circulating the ore within the retort; and a water seal closing the outlet of said retort against the escape of mercury-fumes therefrom.

3. In an amalgamating apparatus a fixed retort; a cylindrical agitator rotatably mounted in said retort adapted to receive the ore and subject it to the mercury-fumes of the retort; a mercury seal closing the inlet of said retort; and a water seal closing the outlet of said retort.

4. In an amalgamating apparatus the combination of a retort; means for heating the same; and an inlet-chute adapted to contain a body of mercury to seal the same against the escape of mercury-fumes from the retort.

5. In an amalgamator, a retort; means for heating the said retort; an inlet-chute adapted to contain a body of mercury to seal the same against the escape of mercury-fumes from the retort; and an ore-conveyor arranged in said chute.

6. In an amalgamator a retort, a rotatable agitator arranged within the retort and consisting of a hollow cylinder having oppositely-directed inner and outer peripheral spiral feeding-flanges as described, a bifurcated inlet-chute within one end thereof adapted to direct the ore to the bottom of the said including retort, the other end of the said cylinder being provided with a means for receiving ore as it is fed forward on the bottom of the retort and for conducting it to the interior of said cylinder, all substantially as described.

7. The combination in an amalgamator of a mercury seal through which the ore is fed; means for feeding the ore through said seal into a retort; an inclined retort discharging into a water seal; a rotatable agitator mounted in said retort adapted to feed the ore forward along the heated bottom of the retort, and to pick up the ore at its forward end and impart to the same a spiral circulation in the interior thereof before discharging it at the rear end thereof.

696,453. HOLDING-TOOL FOR AIR-BRAKE PISTONS. JAMES KOSHER, Chicago, Ill. Filed June 12, 1901. Serial No. 64,572. (No model.)

Claim.—1. In a holding-tool of the class described, the combination of a standard portion adapted to open the hollow piston-rod of an air-brake cylinder and contact with the head thereof, a cross-head provided with a plurality of movable dogs, a relatively non-rotatable inwardly-extending portion arranged between the outer standard portion and the cross-head, and means for moving the cross-head in one direction to extend the dogs into engagement with the hollow piston-rod and in the opposite direction to permit them to collapse from such engagement, substantially as described.

2. In a holding-tool of the class described, the combination of a standard portion adapted to open a hollow piston-rod and detect a cylinder-head thereon, a cross-head provided with a plurality of pivotal dogs, a relatively non-rotatable arm connected with the outer standard portion

and arranged between it and the cross-head, and an operating-belt in engagement with the standard for moving the cross-head in one direction to extend the pivotal dogs and in the opposite direction to permit them to collapse, substantially as described.

3. In a holding-tool of the class described, the combination of a standard portion provided with inwardly-extending legs which open a hollow piston-rod so as to contact a cylinder-head thereon, a cross-head arranged to be moved backward and forward and provided with a plurality of pivotal dogs having serrations or teeth at their free ends, a hollow relatively non-rotatable inwardly-projecting portion on the standard in contact with the free ends of the pivotal dogs, and an operating-belt for moving the cross-head in one direction to extend the pivotal dogs into contact with the tubular piston-rod and in the opposite direction to permit them to collapse, substantially as described.

4. In a holding-tool of the class described, the combination of a standard portion provided with inwardly-extending legs which open a hollow piston-rod so as to contact with a cylinder-head thereon, a cross-head arranged to be moved backwardly and forwardly and provided with a plurality of pivotal dogs having serrations or teeth at their free ends, a relatively non-rotatable inwardly-projecting portion on the standard in contact with the inner portion of the free ends of the pivotal dogs, an operating-belt for moving the cross-head in one direction to extend the pivotal dogs and in the opposite direction to permit them to collapse, and a tension-spring interposed between the relatively non-rotatable projection and the cross-head, substantially as described.

5. In a holding-tool of the class described, the combination of a standard portion adapted to open a tubular piston-rod and provided with inwardly-projecting legs to contact an air-brake cylinder-head thereon, outwardly-projecting leg mechanism forming a supporting-base to rest the mechanism on the ground and an inwardly-projecting tubular portion provided with an annular flange on its inner end, a cross-head provided with a plurality of pivotal dogs extending forward into contact with the annular flange, a tension-spring interposed between the cross-head and the annular flange, and an operating-belt in rotatable engagement with the standard and in threaded engagement with the cross-head to move the same forwardly and backwardly against and with the tension of the spring, substantially as described.

6. In a holding-tool of the class described, the combination of an outer standard portion, a hollow relatively non-rotatable arm, a cross-head provided with a plurality of pivotal dogs adapted to contact with the end of the hollow arm, and a belt connected with the cross-head and arranged to extend through the hollow arm and outer standard portion and moving the cross-head backward and forward, substantially as described.

7. In a holding-tool of the class described, the combination of an outer standard portion, a cross-head provided with movable arms, a relatively non-rotatable portion arranged between the outer standard portion and the cross-head in operative connection with the movable arms on each head, and means for moving the cross-head in one direction to expand the

movable arms thereon and in the opposite direction to permit them to collapse, substantially as described.

8. In a holding-tool of the class described, the combination of an outer standard portion, a movable head portion provided with a plurality of movable arms, a relatively non-rotatable rigid arm portion arranged between the outer standard portion and the head in operative connection with the movable arms on each head, and means for moving the head and movable arms toward the rigid arm to extend the movable arms on each head, and in the opposite direction to permit them to collapse, substantially as described.

696,454. ELECTRICALLY-OPERATED FLOW. MARTIN T. A. KUSCHKE, Berlin, Germany. Filed Oct. 17, 1901. Serial No. 70,951. (No model.)

Claim.—1. A plow having a propelling motor, two sets of shares and means for raising and lowering each set by means of the plow-motor.

2. A plow having an electric propelling motor, two sets of shares, separate mechanism for raising and lowering each set, and means for connecting either mechanism with said motor.

3. A plow having an electric propelling motor, two sets of shares, a vertically-movable carrier for each set, mechanism for operating said carrier, and means for connecting said mechanism with said motor.

4. A plow having an electric propelling motor, two sets of shares, a vertically-movable carrier for each set, upright screws for operating each carrier, gearing for rotating said screws, and means for connecting said gearing with said motor.

5. A plow having an electric propelling motor, two sets of shares, a vertically-movable carrier for each set, gearing for operating said carrier, a movable shaft having a friction-wheel and connected with said gearing, a friction-wheel driven by said motor, and a lever for throwing said friction-wheels together.

6. A plow having a propelling motor and a straight triangular frame, a wheel at each corner thereof, and two sets of shares arranged to work on lines falling inside of the triangular frame.

7. A power-driven plow having a steering-wheel at each end, a right shaft for each wheel, and a right and left hand screw connecting lever-arms on said shafts.

696,455. GLASS-POLISHING MACHINE. WILLIAM LAMBERT ALLEN, Ohio. Filed Nov. 14, 1901. Serial No. 62,368. (No model.)

Claim.—1. In a glass grinding and polishing machine the combination of a supporting vertical post, with a revolvable horizontal arm supported thereon, with means for moving and retaining said arm at different heights, and a revolvable table supported at the free end of said arm, and

a horizontal arm revolvably supported on the top of said post bearing a carriage longitudinally movable thereon, with grinding mechanism supported in said carriage arranged to engage a plate of glass on said table, with mechanism for driving said grinding mechanism, and for moving said carriage along said arm, substantially as shown and described.

2. In a glass-polishing machine having a supporting vertical post, with a revolvable horizontal arm supported thereon with means for moving and retaining it at different heights thereon, and a horizontal table revolvably mounted in the outer end of said arm, a horizontal arm revolvably mounted on the top of said post bearing a carriage adapted to be reciprocated lengthwise thereof, with grinding mechanism mounted on said carriage adapted to engage a plate of glass on said table, and revolvable on said carriage, with mechanism adapted to drive said grinding mechanism, and a clutch arranged to engage said driving mechanism to rotate said grinding mechanism and means for throwing said clutch into and out of engagement, substantially as shown and described.

3. In a glass grinding and polishing machine the combination with a supporting-post of a horizontal arm revolvably mounted thereon and mechanism for raising, lowering and arresting said arm thereon, a horizontal table revolvably mounted in the free end of said arm having sliding ways with a horizontal arm mounted on the top of said post having sliding ways with a carriage mounted thereon, and means for moving said carriage lengthwise thereof, a frame horizontally revolvable on said carriage adapted to bear grinding and polishing machinery, and means for moving said frame vertically on said carriage, with driving mechanism to drive said grinding and polishing mechanism and means as a lever to regulate the pressure of said grinding and polishing mechanism with reference to a plate of glass on said table, substantially as shown and described.

4. In a glass grinding and polishing machine, the combination with a vertical post, a horizontal arm revolvable thereon provided with means for raising and lowering it, a table revolvably mounted on the free end of said arm, a horizontal arm revolvably attached to the top of said post, a carriage slidable on said arm, a screw for driving said carriage along said arm, a frame revolvably supported on and depending from said carriage to retain revolvable grinding and polishing mechanism above and adjacent to said table, driving mechanism mounted in said post connected by intermediate machinery with said grinding and polishing mechanism, means for raising and lowering said frame, and a clutch and intermediate mechanism to cause said driving mechanism to rotate said frame, and means for operating said clutch, substantially as shown and described.

5. An improved table for glass grinding and polishing machines consisting of a metallic plate with a raised rim having a band of wood within said rim and a bed of cement within said wood rim, said wood and cement having their tops in the same horizontal plane, substantially as shown and described.

696,456. RETORT-FURNACE. DAVID LAIRD, Perth, Scotland. Filed Sept. 24, 1901. Serial No. 70,267. (No model.)

Claim.—1. In combination in a retort-furnace, a retort *g*, a dome *a* of fire-clay in which the retort is placed, said dome having below the retort an inclined flame-passage *A*, and around the sides and upper part of the retort a space *c* tapering toward the end of the retort, lateral passages *i* communicating between the flame-passage *A* and the space *c*, a fire-clay bed *f* below the retort upon which the same rests, said fire-clay bed being supported by the dome *a*, and a burner *v* for liquid hydrocarbon or gas, and air under pressure, substantially as described.

2. In combination in a retort-furnace, a retort *g*, a door *l* leading into retort, and a condenser *k*, a dome *a* of fire-clay in which the retort is placed, and plates *d* and door *m* providing access to the retort, an inclined flame-passage below retort, a space *c* around the sides and upper part of the retort, lateral passages *i* communicating between the flame-passage *A* and the space *c*, a fire-clay bed *f* below the retort upon which the same rests and a burner *v*, *u*, substantially as described.

696,457. CARBURIZER. OSCAR A. LASS and HUGHES A. DAVENPORT, Adrian, Mich., assignors to the Adrian Gas Machine Manufacturing Company, Adrian, Mich., a Corporation of Michigan. Filed Apr. 27, 1901. Serial No. 57,791. (No model.)

Claim.—1. In a carburizer, the combination with a tank adapted to contain oil and air thereabove and in contact therewith under pressure, of a retort, a vapor-burner for heating said retort, a valve-controlled pipe connecting the liquid-space of said oil-tank with said retort, and a second valve-controlled pipe connecting the air-space of said oil-tank with said burner, whereby the vapor-entrained air within said oil-tank may be burned to furnish the initial heat to said generator and also form the propelling force for feeding the oil.

2. In a carburizer, the combination with a tank adapted to contain oil and air thereabove and in contact therewith under pressure, of a retort, a vapor-burner for heating said retort, a mixing-tube into which the vapor is directed from said retort and which is connected with the serv-

ice-pipe, a valve-controlled pipe connecting the oil-space of said oil-tank with said retort, a second valve-controlled pipe connecting the air-space of said oil-tank with said vapor-burner and a pipe connecting said mixing-tube with said vapor-burner, for the purpose described.

3. In a carburizer, the combination of a cylindrical burner-assembly open at its upper end and having ears projecting upwardly from opposite sides thereof, a retort in the form of a hollow disk arranged between said ears above said burner, an oil-inlet pipe to said retort passing through an aperture in one of said ears, a valve-controlled vapor-outlet stem projecting upward from said retort, a mixing-tube supported upon said retort in line with the vapor-outlet and a depending apertured leg on said mixing-tube engaging with said oil-inlet pipe and forming a brace.

696,458. COMBINED SPOKE-FASTENER AND TIRE-TIGHTENER. EMMER, ROGER LAVELLE, Grimsdale, Mo. Filed Aug. 24, 1901. Serial No. 79,120. (No model.)

Claim.—In a device of the kind described, the combination of a fully having an opening formed therein, a bolt having a threaded portion and a reduced cylindrical shank extending therefrom that is adapted to fit within the opening in the fully, ribs formed upon the said reduced portion, a ferrule having a wrough-surface formed upon the exterior thereof, the interior of said ferrule having a bore of even diameter throughout its entire length and having one end terminating in a threaded portion, of a spoke adapted to fit within the said ferrule, and an elastic cushion interposed within the said ferrule between the end of the spoke and bolt, substantially as shown and described.

696,459. MEANS FOR PREVENTING CREEPING OF METERS. ALEXANDER D. LOFF, Schenectady, N. Y., assignor to General Electric Company, a Corporation of New York. Filed Oct. 23, 1901. Serial No. 79,879. (No model.)

Claim.—1. In an electric meter, the combination with the rotating member, of an antiscrooping device consisting of a piece of non-magnetic metal or other conductor superposed thereon.

2. In an induction-meter, the combination with the induced member, of an antiscrooping device consisting of a small piece of copper or other good conducting non-magnetic metal superposed thereon.

3. In an induction-meter, an induced member having a locally-thickened portion of non-magnetic material arranged to pass periodically through the field of the meter as the induced member rotates.

4. The combination with the rotating member of an alternating-current induction-meter, of a locally-superposed piece of non-magnetic metal.

5. In an electric meter, the combination with the rotating member, of a plurality of pieces of metal or other good conducting material attached thereto in such positions as to balance each other.

6. The combination with an electric meter, of a piece of metal attached to the rotating member of the meter and operating to prevent creeping of the meter, and means for balancing any turning moment due to the weight of said piece.

696,460. GRAIN-THRESHING MECHANISM. WILLIAM MALONEY, Sherbrooke, Canada, assignor of seven-tenths to Maxwell & Inglis and Isaac Pittblado, Winnipeg, Manitoba, Canada, and Louis T. Watson, Minneapolis, Minn. Filed Apr. 10, 1901. Serial No. 55,552. (No model.)

Claim.—1. In a combined harvester and thrasher adapted to advance through standing grain, a threshing mechanism mounted on the machine-frame in an exposed position and comprising a series of upright threshing-bars having the working faces exposed to access directly by the heads of the standing grain, and a series of revolving elements operatively related to said working faces of the threshing-bars, the diameter of said revolving elements exceeding the width of the threshing-bars, whereby the revolving elements project well in front of the threshing-bars and are adapted to sweep or carry the heads of standing grain between the bars, substantially as described.

2. In a combined harvester and thrasher adapted to advance through standing grain, a threshing mechanism mounted on the machine-frame in an exposed position and comprising a series of upright bars disposed in spaced relation and each having working faces in opposing relation to similar faces on other bars and said faces exposed to access directly by the heads of standing grain, and a series of revolving disks each having working faces in opposing relation to similar faces on the adjacent bars, the diameter of said disks exceeding the width of the bars, whereby the disks project beyond the bars and are adapted to sweep or carry the heads of grain between the cooperative working faces, substantially as described.

3. In a combined harvester and thrasher adapted to advance through standing grain, a threshing mechanism mounted on the machine-frame in an exposed position and comprising a series of revolving disks provided with lateral working faces, and a series of upright bars having the working faces thereof exposed to access directly by the heads of standing grain and in cooperative relation to the similar faces on the revolving disks, said threshing-bars being adjustable laterally and in parallel relation to an adjacent disk, whereby the width of the grain throat or space between the bars and disks may be increased or diminished, substantially as described.

4. In a combined harvester and thrasher adapted to advance through standing grain, a threshing mechanism mounted on the machine-frame in an exposed position and comprising a series of revolving disks provided with lateral working faces, and a series of upright bars having working faces in opposing relation to the similar faces of the disks, the diameter of each disk exceeding the width of the bar adjacent thereof, each upright bar having forwardly-converging guide-faces disposed in front of the working faces thereof and forming a narrow crest at the front edge of said bar, substantially as described.

5. In a combined harvester and thrasher adapted to advance through standing grain, a threshing mechanism mounted on the machine-frame in an exposed position and comprising a series of revolving disks provided with working faces, and a series of threshing-bars alternating with the disks and provided with working faces in opposing relation to the disks and exposed to access directly to the heads of standing grain, each threshing-bar consisting of complementary members provided with rearwardly-

diverging grain-deflecting surfaces which extend from a narrow crest on the bar substantially to the working faces thereof, as set forth.

6. In a combined harvester and thrasher adapted to advance through standing grain, a threshing mechanism mounted on the machine-frame in an exposed position and comprising a series of revolving disks provided with working surfaces, and a series of upright bars having working faces in opposing relation to the disks and adapted to direct access by the heads of standing grain, the diameter of the disks exceeding the width of the bars, each bar consisting of complementary members provided with forwardly-converging grain-deflecting surfaces and said members being adjustable laterally with respect one to the other and to the working faces of the disks, substantially as described.

7. A threshing mechanism comprising a series of revolving disks having the working faces, and a series of threshing-plates alternating with the disks, each threshing-plate consisting of members which are seated upon a suitable support and are connected adjustably thereto and stayed adjustably with relation to each other, said plate members having working surfaces at the rear portions thereof and in opposing relation to the working faces of the disk, substantially as described.

8. A threshing mechanism comprising a series of revolving disks, a series of stationary threshing elements, and dividers extending in front of said stationary elements and having lateral bulged portions in operative relation to said elements, substantially as described.

9. A threshing mechanism comprising a series of revolving elements, a series of upright elements in cooperative relation to the revolving elements, and a series of dividers mounted upon the upright elements and projecting in advance thereof, each divider consisting of curved members united at their front ends and attached at their rear ends to the element, substantially as described.

10. In a combined harvester and thrasher adapted to advance through standing grain, the combination of a shaking-riddle, a series of exposed upstanding threshing-plates disposed in advance of the riddle and having working faces exposed to access directly by the heads of standing grain, a series of exposed revolving disks having working faces in opposing relation to the similar faces of said bars and revolving in a direction to sweep grain between the bars and over the riddle, and a blast mechanism arranged to direct a blast rearwardly across the riddle, substantially as described.

11. In a combined harvester and thrasher adapted to advance through standing grain, the combination of a shaking-riddle, upstanding exposed threshing-bars in advance of the riddle, revolving disks between said threshing-bars and revolving in a direction to sweep the heads of standing grain between the bars and to carry the grain over the riddle, a forwardly and downwardly inclined blast-plate at the rear portion of the riddle, and a blast-fan having its wind-trunk arranged to discharge a blast upwardly and rearwardly through the riddle, substantially as described.

12. In a combined harvester and thrasher adapted to advance through standing grain, the combination of a casing having a curved bottom forming a conveyor-belt, a carrying-bar at the front edge of the casing, a shaking-riddle arranged within said casing, a series of exposed threshing-bars erected on said carrying-bar and disposed in advance of the riddle, revolving disks in cooperative relation to said threshing-bars and arranged to sweep grain between the bars and over the riddle, a blast mechanism delivering a wind-current across the riddle, and a conveyor operatively disposed in said housing below the riddle, substantially as described.

13. In a combined harvester and thrasher adapted to advance through standing grain, the combination of a casing provided at its rear side with a chaff-escape opening, a shaking-riddle supported in said casing contiguous to said opening therein, a series of exposed threshing-bars erected at the front edge of the casing and in advance of the riddle, a like series of exposed disks revolving in a direction to sweep grain between the bars and over the riddle, a blast-fan, and a wind-trunk arranged to discharge a current of air in fan upward and rearward direction through the riddle and toward the chaff-escape opening, substantially as described.

14. In a combined harvester and thrasher adapted to advance through standing grain, a threshing mechanism mounted on the machine-frame in a position exposed to access directly by the heads of standing grain and comprising a series of threshing-bars provided with opposing working faces, each bar having at its base a deflected or curved portion arranged in cooperative relation to a similar portion on an adjacent bar and forming an enlarged clearance space or throat for the discharge of threshed grain, and exposed revolving disks arranged to sweep grain between the threshing-bars and to cooperate with the latter in threshing the grain, substantially as described.

15. In a combined harvester and thrasher adapted to advance through standing grain, a threshing mechanism mounted on the machine-frame in a position exposed to access directly by the heads of standing grain and comprising a series of threshing-bars and a series of revolving disks in cooperative relation to the threshing-bars, each threshing-bar comprising a pair of complementary members disposed back to back and having the forwardly-converging grain-deflecting surfaces, substantially as described.

16. In a combined harvester and thrasher adapted to advance through standing grain, an exposed threshing-bar comprising complementary members having the forwardly-converging grain-deflecting surfaces meeting in a central ridge or crest, working faces on the exposed surfaces of the members, and means for adjustably connecting the members, combined with revolvable disks disposed in cooperative relation to a series of such threshing-bars, substantially as described.

17. In a combined harvester and thrasher adapted to advance through standing grain, the combination of a carrying-bar, a series of upstanding threshing-bars each having complementary members disposed back to back and said members fastened adjustably to said carrying-bar, said members of each threshing-bar having the exposed working faces and the grain-deflecting faces, means for rigidly and adjustably connecting the members of each threshing-bar together, and revolvable disks in cooperative relation to the threshing-bars, substantially as described.

696,461. SPRING AIR-GUN. WILLIAM F. MARRAS, Plymouth, Mich. Filed July 2, 1900. Serial No. 22,206. (No model.)

Claim.—1. In a spring air-gun, the combination of the outer or false barrel, a sleeve secured in the forward end thereof and provided with a slot, and the true barrel and muzzle-cap secured together and provided with a projection cooperating with said slot to lock them in position, substantially as described.

2. In a spring air-gun, the combination of the outer or false barrel, a sleeve secured in the forward end thereof and provided with a cam-dot, and the true barrel and muzzle-cap permanently secured together and provided with a projection cooperating with said cam-dot to force said barrel and cap inward and outward by turning them in opposite directions, and to lock them in position, substantially as described.

3. In an air-gun, the combination of a false barrel, a removable true barrel fitting therein, and means carried by the respective barrels adapted to engage and cooperate to rotate the true barrel as it is inserted or withdrawn, substantially as described.

4. In a spring air-gun, the combination of the outer or false barrel, a tubular wooden plug inserted therein, a metal sleeve or bushing permanently secured therein between the wooden plug and the muzzle of the gun and operating to hold said wooden plug in position against the blows of the piston, the true barrel seated in the central bore of said plug, and the muzzle-cap fitting over the forward end of said sleeve and detachably connected thereto, substantially as described.

5. In a spring air-gun, the combination of the outer or false barrel, a tubular wooden plug inserted therein, a metal sleeve or bushing permanently secured therein between the wooden plug and the muzzle of the gun and operating to hold said wooden plug in position against the blows of the piston, the true barrel seated in the central bore of said plug, and the muzzle-cap permanently secured to the outer end of the true barrel and fitting over and detachably connected with the sleeve secured in the outer barrel, substantially as described.

6. In a spring air-gun, the combination of the outer or false barrel, a tubular wooden plug inserted therein, a metal sleeve or bushing permanently secured therein between the wooden plug and the muzzle of the gun and operating to hold said wooden plug in position against the blows of the piston, the true barrel seated in the central bore of said plug, the muzzle-cap secured to the forward end of said barrel and fitting over the extremity of the sleeve secured in the outer barrel, and a bayonet-lock for detachably connecting the true barrel and muzzle-cap to said sleeve and outer barrel, substantially as described.

7. In a spring air-gun, the combination of the barrel B, the tubular wooden plug I inserted therein, the metal sleeve J permanently secured in the barrel B and provided with the slot N adjacent the muzzle of the gun, the true barrel L seated in the bore of the plug I and provided with the projection O cooperating with the slot N, and the muzzle-cap M secured to the extremity of the barrel L and fitting over the forward end of the sleeve J, substantially as described.

8. In a gun, the combination of an outer or false barrel, a sleeve held therein and projecting outward slightly beyond the end of the same, a true barrel, and a muzzle-cap supporting the forward end of the true barrel and fitting over the projecting end of the sleeve in the false barrel, substantially as described.

9. In a spring air-gun, the combination of the outer or false barrel, a plurality of leather washers secured therein at the forward end of the compression-chamber and constituting both an abutment for the piston and a seat for the rear end of the true barrel, the true barrel seated at

its rear end in said washers and supported at its forward end in the muzzle-cap, and means for detachably securing said true barrel and muzzle-cap in position and producing a twisting movement of the barrel at the insertion and withdrawal of its rear end from its seat in the leather washers, substantially as described.

10. In a spring air-gun, the combination of the outer or false barrel, the tubular wooden plug therein, the plurality of leather washers secured to the rear end of said plug and constituting an abutment for the piston and a seat for the rear end of the true barrel, the true barrel seated at its rear end in said washers and supported at its forward end in the muzzle-cap, and means for detachably securing said true barrel and muzzle-cap in position and producing a twisting movement of the barrel at the insertion and withdrawal of its rear end from its seat in the leather washers, substantially as described.

11. In a spring air-gun, the combination of the outer or false barrel, the plurality of leather washers secured therein at the forward end of the compression-chamber, the metal washer interposed between said leather washers and having a central aperture smaller than the bore of the true barrel, the true barrel seated at its rear end in the leather washers and supported at its forward end in the muzzle-cap, and means for detachably securing said true barrel and muzzle-cap in position, substantially as described.

12. In a spring air-gun, the combination of the outer or false barrel, the tubular wooden plug therein, the plurality of leather washers and the interposed metal washer secured to its rear end, said metal washer having a central aperture smaller than the bore of the true barrel, the true barrel supported at its rear end in said wooden plug and seated at its extremity in the leather washers, the muzzle-cap secured to the forward end of the true barrel, and means for detachably securing said true barrel and muzzle-cap in position, substantially as described.

13. In a spring air-gun, the combination of the barrel B, the wooden plug I therein, the leather washers C D and interposed metal washer J secured to the rear end of the plug I, the sleeve J permanently secured in the front end of the barrel B and serving to hold the plug I in position, the true barrel L passed through the plug I and seated at its rear end in the washers C D, the muzzle-cap M secured to the front end of the barrel L and fitting over the extremity of the sleeve J, and means for detachably connecting the barrel L and the cap M to said sleeve, substantially as described.

14. In a spring air-gun, the combination of an outer or false barrel, a plurality of flexible washers secured therein at the forward end of the compression-chamber, a true barrel seated at its rear end in said washers and supported at its forward end in the muzzle-cap, and means for detachably securing the true barrel and muzzle-cap in position, substantially as described.

15. In an air-gun, the combination of a false barrel, a removable true barrel fitting therein, and means for causing the true barrel to rotate as it is inserted or withdrawn, substantially as described.

16. In a spring air-gun, the combination of the outer or false barrel, a tubular plug inserted therein, a metal sleeve or bushing held against longitudinal movement therein between the tubular plug and the muzzle of the gun and operating to hold said plug in position against the blows of the piston, a true barrel seated in the central bore of said plug, and a muzzle-cap at the forward end of said sleeve, substantially as described.

17. In a spring air-gun, the combination of the outer or false barrel, a sleeve held therein and provided with a cam-dot, a true barrel, and means carried by the true barrel cooperating with said cam-dot to force said barrel inward and outward by turning them in opposite directions, substantially as described.

18. In a spring air-gun, the combination of an outer or false barrel, a flexible washer secured therein at the forward end of the compression-chamber, a removable true barrel seated at its rear end in said washer and supported at its forward end in the muzzle-cap, and means for twisting the true muzzle as the same is forced inward and outward, substantially as described.

696,462. KITCHEN-TABLE. CHARLES L. HARTSHORN, Chicago, Ill. Filed Dec. 29, 1900. Serial No. 41,437. (No model.)

Claim.—1. In a kitchen-table, the combination with a suitable top and supporting-legs, of the frame, K, comprising substantially the horizontal portion, A, adapted to be attached to the rear side of the table, and the upright portion, B, adapted to be secured to the top of the table, a dividing-strip secured in the horizontal portion of the frame and rollers journaled in the horizontal portion on each side of the dividing-strip, corresponding frames, M, secured at the ends of the table and the drawers, O, O', provided with suitable strips running upon said rollers, substantially as described.

2. In a kitchen-table, the combination with a suitable top and supporting-legs, of the supporting-frame, K, M, M, provided with supporting-rollers and the drawers, O, O', provided with suitable strips running

upon the rollers and with the blocks, Y, Y, adapted to engage the under sides of the frames to prevent the tilting of the forward portion of the drawers when drawn out beyond their center of gravity, substantially as described.

696,463. LIFT-RAFT. DANIEL G. MARTIN, London, England. Filed Apr. 27, 1901. Serial No. 57,600. (No model.)

Claim.—In a ship or vessel fitted with detachable flexible sections or rafts resting on the deck house or houses, means for launching the rafts, comprising raising-levers pivoted to the deck house or houses and adapted when turned to raise and support the raft above the roof of the deck house or houses, and swinging mechanisms pivoted to and turning on the taffrail or other fixed part of the vessel and carrying rollers on their extremities, said mechanisms being normally held upright by powerful springs and maintained in that position by a cord or the like detachable means, substantially as described.

696,464. STATION-INDICATOR. JOSEPH A. MEAD, Cleveland, Ohio. Filed July 27, 1901. Serial No. 69,962. (No model.)

Claim.—1. In a station-indicator, a name-strip, a drum for winding up the name-strip, intermittent actuating mechanism for the said drum embodying a clutch-lever, a stop for limiting the forward movement of the clutch-lever, and means for adjusting the position of the said stop and controlled by variation or change in the diameter of the drum incident to the winding of the name-strip thereon, substantially as set forth.

2. In a station-indicator, a name-strip, a drum, intermittently-actuated mechanism for winding the name-strip upon the drum and including a clutch-lever, a stop for holding the clutch-lever in a normal position and limiting its return throw, an adjustable stop for limiting the forward throw of the said clutch-lever, and means controlled by the change in diameter of the said drum to vary the position of the adjustable stop to admit of a like amount of the name-strip being wound upon the drum at each actuation thereof, substantially as set forth.

3. In a station-indicator, companion drums, a name-strip adapted to wind upon one of the drums and unwind from the other drum, intermittently-actuated means for one of the drums including a clutch-lever, a stop for limiting the forward movement of the said clutch-lever, and means for changing the position of the said stop proportionate to the variation in the diameters of the two drums, said means embodying cooperating elements in contact with the respective drums, substantially as set forth.

4. In a station-indicator, companion drums, a name-strip, intermittently-actuated means for winding the name-strip upon one of the drums and unwinding it from the other drum and including a clutch-lever, a stop for limiting the forward throw of the clutch-lever, adjustable plates operatively connected with the said stop to effect a change in position thereof, and elements supported by the said plates and in contact with the respective drums and controlled by the change in diameter thereof incident to the unwinding of the strip from one drum and the winding thereof upon the other drum to effect a shifting of the aforementioned stop, substantially as set forth.

5. In a station-indicator, cooperating drums, a name-strip, intermittently-actuated means for one of the drums including a clutch-lever, a slidably-mounted frame having a portion extended in the path of the clutch-lever to limit its forward movement, pivoted plates or levers provided with elements in contact with the respective drums, means for securing the said plates in an adjusted position, and a connection between one of the said plates and the slidable frame, the elements supported by the said plates being in line with the axis of the said drums and the distance between the pivotal support for the said plates and the elements carried thereby at the point of contact with the slidable frame being substantially equal, as and for the purpose set forth.

6. In a station-indicator, cooperating drums, intermittently-actuated means for the said drums comprising clutch-levers, a slidable frame having portions extended in the path of the said clutch-levers to limit their forward movement, and means controlled by the change in diameter of the drums to vary the position of the slidable frame and the consequent forward throw of the clutch-levers, substantially as set forth.

7. In a station-indicator, cooperating drums, a name-strip, intermittently-actuated means for the drums to effect a winding of the name-strip thereon, flanges rotatable with the drums, plates having the flanges be-

tween them, and means for adjusting the said plates to grip the flanges more or less tightly to prevent the too free movement of the drums, substantially as set forth.

696,465. CORSET. **PATENT J. MERRAN,** Brooklyn, N. Y. Filed Jan. 22, 1900. Serial No. 2,465. (No model.)

Claim.—In a corset, a system of stays composed of a stiffer and reinforce individually connected by their ends so as to be movable relatively to each other and provided with a layer of paper between them in addition to the cloth, so as to increase their freedom of motion, substantially as described.

696,466. SAILING-MACHINE. **HENRY W. MORRAN,** Rochester, N. Y. Filed Mar. 10, 1900. Serial No. 706,466. (No model.)

Claim.—1. In a sailing-machine, the combination with the main frame, the work-support and the vertically-movable cross-head, the laterally-adjustable arms 8 on the cross-head, the driver-brackets adjustable longitudinally of the arms, and the drivers, carried by the brackets and arms and adjustable thereon, the cross-bar 16 on the main frame, the brackets 17 adjustable thereon, the laterally-extending brackets 20, and nail-holding checks adjustable upon the brackets 17 and 20.

2. In a sailing-machine, the combination with the main frame and work-support, a cross-bar such as 16 on the frame, a pair of relatively adjustable check-supporting brackets on the bar, check-supporting brackets extending laterally from the last-mentioned brackets and adjustable thereon, and nail-holding checks adjustably secured to each of said brackets, of nail-drivers operating in the checks, and means for operating them.

3. In a sailing-machine, the combination with the main frame, the work-support, the vertically-movable cross-bar, the relatively adjustable driver-brackets mounted on the cross-bar having the clips in their lower sides, the driver-brackets extending laterally of the first-mentioned brackets and adjustable thereon toward and from the cross-bar on the frame and the drivers adjustable on their brackets, of the nail-checks supported below the driver-brackets and with which the drivers cooperate and adjustable on their supports.

4. In a sailing-machine, the combination with the main frame and the cross-bar 16 thereon, of a pair of forwardly-extending check-supports secured to and adjustable upon said bar, a pair of laterally-extending check-supports mounted upon the supports on the bar and adjustable longitudinally thereon, nail-holding checks mounted adjustably upon the supports, two of said checks having the downwardly-extending arms for centering the work, and nail-drivers operating in the checks and adjustable with the checks.

696,467. GLASS-WORKING MACHINE. **FRANK R. McLENNAN,** Evanston, Ill., assignor to the Western Electric Company, Chicago, Ill., a Corporation of Illinois. Filed July 15, 1900. Serial No. 696,467. (No model.)

Claim.—1. The combination in a glass-working machine, of a hollow spindle and a chuck having jaws carried upon the end of said spindle, said spindle being adapted to receive an indefinite length of straight glass tubing through its open end, and permitting the tubing to be thrust through the bore of the spindle and protrude through the jaws of the chuck, the jaws of the chuck being adapted to engage and hold the tubing, a second chuck in alignment with the first, adapted to hold the end of the tubing which protrudes from the first-mentioned chuck, means for heating the checks at equal speeds in the same direction, a gas-jet for heating the glass tubing at a point between the two chucks, and means for causing relative longitudinal movement between the chucks, whereby the glass tubing is drawn out, as described.

2. In combination, in a glass-working machine, two hollow rotatable spindles in alignment with one another, adapted to receive straight glass tubing of indefinite length, fed through said spindles from end to end, a chuck carried by each spindle, each of said chucks having jaws adapted to grasp the tubing a gear on each spindle and a pinion for each gear longitudinally movable on a shaft having a spline engaging said pinions, means for driving said shaft, a gas-jet directed upon the glass tubing between the two spindles, and mechanism for causing a relative longitudinal movement of the chucks, whereby the tubing is drawn out, as described.

3. The combination with the longitudinally-movable stocks and the hollow spindles journaled therein, said spindles being in alignment and adapted to receive straight glass tubing of indefinite length, fed through said spindles from end to end, the gears on the spindles and the pinions meshing into said gears as a spindle shaft, and means for rotating said spindles, of the chucks carried by the hollow spindles, the gas-jet carried between said chucks, the lever 22 and the links 23 connecting said lever with the stocks carrying the chucks, as described.

696,468. FOLDING BOX. **BENJAMIN R. McFARLANE,** Washington, D. C. Filed Feb. 6, 1901. Serial No. 46,515. (No model.)

Claim.—1. The herein-described folding-box blank, embodying the bottom, top, ends and sides in one piece and foldable into box-like form, the top being in two sections adapted to be united intermediate of the box, and the ends having reinforced guard-flaps to fold over the ends of the two-part top, the flaps being provided with means to constitute one member of a fastening device to coast with a second member carried by the box-top.

2. The herein-described folding-box blank embodying the bottom, top, ends and sides in one piece and foldable into box-like form, the top being in two sections adapted to be united intermediate of the box, the sides having flaps integral therewith to be folded inward to form closures for the ends of the box, guard-flaps carried by the ends proper and adapted to fold over the ends of the two-part top, and a two-part metallic fastening device, one member of which is carried by the top and the other member by the guard-flap.

3. The herein-described folding-box blank embodying the bottom, top, ends and sides in one piece and foldable into box-like form, the ends having guard-flaps integral therewith and reinforced by folding the outer edge over upon the body of the end section, and fastening means for securing the ends to the top, said means being connected with the guard-flaps and with the said top.

4. The herein-described folding box embodying the top, bottom, ends and sides in one piece and foldable into box-like form, the top being in two sections, to be secured permanently together prior to the assembling of the other parts of the blank and constituting no part of the ends of the box, and two-membered metallic fastening devices one member being secured to the top and carrying as holding means for the two sections thereof, and the other member being secured to the ends proper.

5. The herein-described folding box embodying the bottom, top, ends and sides in one piece and foldable into box-like form, the top being in two sections and adapted to be united intermediate of the box, the ends of the box having guard-flaps formed by folding the outer edge over the body of the end closure, and two-membered fasteners to hold the ends in folded position with relation to the top, one member being secured to the top and the other member being secured between the folds of the guard-flap.

6. The herein-described folding box embodying the bottom, top, ends and sides in one piece and foldable into box-like form, the top being in two sections and constituting no part of the ends of the box, fasteners adapted to unite the adjacent parts of the top sections independently of the other parts of the box, and means whereby the same fasteners are utilized to secure the ends of the box in operative position.

7. The herein-described folding box embodying the bottom, top, ends and sides in one piece and foldable into box-like form, the top being in two sections adapted to be secured together independently of, and prior to the assembling of, the other parts of the box, said top constituting no part of the ends of the box, and fasteners adapted to secure the ends of the box to the top, the same fasteners serving as holding means for the sections of the top.

8. The herein-described folding box embodying the bottom, top, ends and sides in one piece and foldable into box-like form, the top being in two overlapping sections to be secured together prior to the assembling of the other parts of the box, said top constituting no part of the ends of the box, fasteners adapted to unite the adjacent parts of the overlapping top sections, and means coacting with the fasteners and carried by the ends proper to secure the ends of the box in position.

9. The herein-described folding box embodying the bottom, top, ends and sides in one piece and foldable into box-like form, the top being in two sections adapted to be secured together independently of the other parts of the box, said top constituting no part of the ends of the box, one member of a fastener secured to said top, and a corresponding member of said fastener secured to the adjacent foldable end.

10. The herein-described folding box embodying the bottom, top, ends and sides in one piece and foldable into box-like form, the top being in two sections to be permanently secured together prior to the assembling of the other parts of the box, the ends having guard-flaps integral therewith and reinforced by folding the outer ends over upon the body of

the end sections, and fastening means for securing the folded ends to the top, said fastening means being connected with the guard-flaps and the box-top.

11. The herein-described folding box embodying the bottom, top, ends and sides in one piece and foldable into box-like form, the end parts having guard-flaps integral therewith and reinforced by folding the outer edge over upon the body of the end sections, the top section being in two parts and to be secured together prior to the assembling of the other parts of the box, and a two-membered metallic fastener device for securing the ends of the top, one member of the fastener being attached to the top of the box and serving as an additional means of holding the top sections assembled, and the other member of the fastener being secured between the members of the guard-flap.

696,469. ART OF TREATING ORES. **BENNETT McLENNAN,** Philadelphia, Pa. Filed Aug. 12, 1901. Serial No. 71,607. (No specimens.)

Claim.—1. The art of treating ores containing precious metal in a flux state and also in larger particles, which consists in heating with free access of air and agitation, a mixture of the ore, containing a refractory metalloid and a haloid salt of an alkaline or alkaline-earth metal, until a haloid salt of the precious metal is produced and volatilized and the corner particles of the precious metal have their surface coatings removed, and the alkaline or alkaline-earth metal unites with the oxygen of the air and with the refractory metalloid, to form a stable oxy-salt, reflecting the volatilized haloid or oxyhaloid of the precious metal, and treating the cleaned particles by amalgamation, substantially as described.

2. The art of treating ores which contain precious metal in a flux state and also in larger particles, coated with carbonates which consist in heating a mixture of the ore a refractory metalloid, and a haloid salt of an alkaline or alkaline-earth metal, with free access of air and agitation, until the carbonic-acid radical of the carbonate upon the surface of the larger particles is driven off, and the material temporarily in combination therewith is changed into a solid or soluble and containing the heating until these solids are changed into oxides, and the haloid salt of the alkaline or alkaline-earth metal is decomposed, and the resultant halogen combined with the finer particles of the precious metal, and the alkaline or alkaline-earth metal combined with oxygen and the refractory metalloid to form a stable oxy-salt of the refractory metalloid, and the alkaline or alkaline-earth metal, volatilizing and collecting the volatilized haloid salt or oxyhaloid salt of the precious metal and treating the cleaned particles by amalgamation, substantially as described.

696,470. BATH-BRUSH. **WILLIAM A. McLENNAN, R. CHRISTIAN,** Ohio. Filed Nov. 20, 1901. Serial No. 63,774. (No model.)

Claim.—An article of toilet, substantially as specified, the same consisting of a rotary brush, and handles having their inner end portions bent toward each other and loosely connected with the brush to admit of free rotation and independent play thereof, substantially as specified.

696,471. AUTOMATIC PRESSURE-GOVERNOR. **JOHN W. FREN,** Cincinnati, Ohio. Filed July 24, 1901. Serial No. 61,741. (No model.)

Claim.—1. In a pressure-governor for controlling fluids under pressure a valve-casing having its inlet-opening in a different horizontal plane from its outlet-opening, a valve within the casing having adjacent to the outlet-opening an imperforate and portion to be carried over the outlet-opening to restrict the same and an upper portion above the inlet-opening and connected to the imperforate and portion to balance a pressure thereon, a spring to hold the valve in its normal position, and a channel for communicating the pressure to be controlled to the valve to move it when said pressure varies from that of the spring, substantially as shown and described.

2. In an automatic pressure-governor for engines the combination

of a valve-rod having its inlet-opening upon a higher horizontal plane than its outlet-opening, a cylindrical valve within the casing consisting of a lower imperforate and portion adjacent to the outlet-opening an upper disk above the inlet-opening and connected to the lower portion, a spring bearing upward against the valve, a governing-chamber upon top of the case, a piston within the chamber, a rod connecting the upper end of the valve and the piston and channel for communicating the pressure against which the engine works to the piston, substantially as shown and described.

3. In a pressure-governor the combination of a casing having its inlet-opening upon a higher horizontal plane than its outlet-opening, within the casing a hollow cylindrical valve having closed ends and longitudinal slots in its sides leaving an imperforate portion at its lower end adjacent the outlet-opening, a spring bearing upward against the valve, a second balanced valve within the lower end of the casing, a governing-chamber upon the upper and upon the lower ends of the casing, a piston within the chamber, a rod connecting the upper piston with the first valve a second rod connecting the lower piston with the second valve, a valve controlling the entrance to the lower governing-chamber which is to be opened only by a pressure exceeding a certain limit, and means for communicating the pressure of discharge to the piston within the upper governing-chamber and to the valve controlling the entrance to the lower governing-chamber, substantially as shown and described.

696,472. STUD. FRANK NEWMAN, Bensenville, Germany. Filed May 26, 1901. Serial No. 62,234. (No model.)

Claim.—The herein-described necktie-fastener, consisting of a stud having an expanded base, a flattened shank, and a head which is elliptical in cross-section, the longest diameter of said head extending parallel to the longest diameter of the shank, and a socket member adapted to be attached to a cravat and to be radially engaged with the head of the stud.

696,473. AUTOMATIC REGULATOR FOR ELECTRIC CIRCUITS. FRANK G. NEWMA, Westinghouse, Pa., assignor to the Westinghouse Air Brake Company, Pittsburgh, Pa., a Corporation of Pennsylvania. Filed Apr. 29, 1908. Serial No. 14,967. (No model.)

Claim.—1. An automatic regulator for electric circuits, comprising a normally open short-circuit, two contact-plugs for the short-circuit, a solenoid having a movable core, and a rod operated by said core and carrying two contact-plugs adapted to close the short-circuit when an excessive current passes through the solenoid.

2. An automatic regulator for electric circuits, comprising a normally open short-circuit, a resistance-coil in the short-circuit, a spring-block of insulating material, two contact-plugs for the short-circuit secured to the block, a solenoid, a movable core therefor provided with a rod carrying

two contact-plugs at its outer end adapted to close the short-circuit when an excessive current passes through the solenoid.

3. An automatic regulator for electric circuits, comprising a normally open short-circuit having a resistance-coil, a block of insulating material, two contact-plugs for the short-circuit spaced apart upon the insulating-block, a solenoid having a movable core provided with a head which is adapted to rest against the insulating-block when the switch is in its open position, and a switch connected to said head and having two contact-plugs for closing the short-circuit.

4. An automatic regulator for electric circuits, comprising a casing, a normally open short-circuit having a resistance-coil in the casing, a solenoid carried by the casing and having a movable core provided with a head, a block of insulating material secured to the casing, two contact-plugs for the short-circuit carried by the insulating-block and a switch connected to said head and having two contact-plugs for closing the short-circuit when an excessive current passes through the solenoid.

5. An automatic regulator for electric circuits, comprising a casing, a short-circuit having resistance coils in the casing, a solenoid mounted in a vertical position on the casing, a stop secured to the casing and adapted to support the movable core of the solenoid when the short-circuit is open and a switch in the short-circuit operated by the solenoid.

6. In an electric system, a generator, a generator-circuit, a short-circuit around the field of the generator, said short-circuit being normally open, a solenoid in the generator-circuit, two contact-plugs in the short-circuit, a rod connected to the movable core of the solenoid and carrying two contact-plugs adapted to close the short-circuit when the current in the generator-circuit is excessive.

7. In an electric system, a generator, a generator-circuit, a short-circuit around the field of the generator, a solenoid in the generator-circuit, a movable core for the solenoid, a stop for supporting the movable core in its outer position when the short-circuit is open and a switch in the short-circuit operated by the solenoid.

696,474. VIBRATO-CONTINUOUS ATTACHMENT FOR PIANOS. HENRY H. BOCHNER, Chicago, Ill. Filed Mar. 12, 1901. Serial No. 61,908. (No model.)

Claim.—1. A vibrato-continuous attachment for pianos, comprising a device for engaging and vibrating the hammers, a rotary momentum-wheel, a pedal mounted to act as a lever, suitable power-transmitting connection between said pedal and said momentum-wheel, power-transmitting connection including a clutch between said wheel and said device for engaging and vibrating the hammers, and suitable connection between the said clutch and said pedal, whereby the latter can be employed for

both raising the wheel and opening and closing said clutch, substantially as described.

2. A vibrato-continuous attachment for pianos, comprising a device for engaging and vibrating the hammers, a pedal mounted to act as a lever, a power-transmitting connection between the said pedal and said device for vibrating the hammers, said power-transmitting connection including a clutch, and suitable connection between said clutch and said pedal, whereby the said pedal can be employed for both operating the power-transmitting connection and opening and closing said clutch, substantially as described.

3. In a piano, the combination of the hammers, a cam arranged back of said hammers and in position to engage arms on the same, a pedal mounted to act as a lever, power-transmitting connection between said cam and said pedal, said power-transmitting connection including a clutch for continuing and discontinuing the transmission of power, and suitable connection between said clutch and said pedal, whereby the latter is adapted for both driving the power-transmitting connection and opening and closing said clutch, substantially as described.

4. In a piano, the combination of the hammers, arms on said hammers, a cam arranged back of the hammers and in position to engage said arms when the keys of the piano are maintained in a depressed position, a power-transmitting connection for driving said cam, said connection including a clutch, and means for opening said clutch as to either continue or discontinue the rotation of said cam, the latter when at rest allowing the said arms on the hammers to swing back and forth for the full stroke of the hammers, substantially as described.

5. In a piano, the combination of the hammers, rearwardly-projecting arms on said hammers, a cam having a single projection or node and arranged back of said hammers in position to engage the ends of said arms, a power-transmitting connection for driving said cam, said power-transmitting connection including a clutch for continuing and discontinuing the rotation of said cam, the clutch when open permitting the cam to remain at rest while the said power-transmitting connection is still running, and the projection or node of the cam when the latter is at rest pointing downwardly, as to permit the said arms on the hammers to swing back and forth for the full stroke of the hammers, substantially as described.

6. The combination in a piano with hammers, of a device for engaging and vibrating said hammers when the keys of the piano are maintained in a depressed position, a rotary motor for driving said device, and a pedal connected and arranged for both driving said motor and independently thereof controlling the operation of said device, said pedal having power-transmitting connection with said motor, said motor having a power-transmitting connection with said device for engaging and vibrating the hammers, and a device for controlling the transmission of power from said motor to said device for vibrating the piano-hammers, said controlling device having a separate and independent connection with the power-transmitting connection interposed between said pedal and said motor, whereby said pedal can be employed for both driving said motor and closing the power-transmitting connection between the motor and said device for vibrating the hammers, substantially as described.

7. In a piano, the combination of the hammers, arms on said hammers, a rotary cam arranged in position to engage said arms, means for driving said cam, a clutch arranged between said driving means and said cam and a pedal connected with said clutch and arranged for controlling the transmission of power from said driving means to said cam, the pedal when at rest rendering the power-transmitting connection inoperative, substantially as described.

8. In a piano, the combination of the hammers, a device for vibrating said hammers, a rotary momentum-wheel, suitable power-transmitting connection including a clutch between said wheel and said device, and a pedal connected with said clutch and arranged for controlling the transmission of power between said wheel and said device, the pedal when in its at-rest position rendering the said power-transmitting connection inoperative, substantially as described.

9. In a piano, the combination of the hammers, a device for vibrating the hammers, a rotary momentum-wheel, suitable power-transmitting connection between said wheel and said device, said power-transmitting connection including a clutch, a pedal adapted and arranged for both rotating said wheel and controlling said clutch, the pedal when at rest holding the clutch open and thereby rendering the said power-transmitting connection inoperative, substantially as described.

10. In a piano, the combination of the hammers, a cam for vibrating said hammers, a rotary momentum-wheel, suitable power-transmitting connection between said wheel and said cam, said power-transmitting connection including a clutch, a pedal mounted to act as a lever, suitable power-transmitting connection between said pedal and said wheel, said pedal being connected and arranged for controlling said clutch, the pedal when at rest holding said clutch open and thereby rendering the said power-transmitting connection inoperative, and the said pedal when depressed

and vibrated permitting the clutch to automatically close and opening to rotate the said wheel, substantially as described.

11. The combination in a piano, of the hammers, a cam for vibrating said hammers, a rotary momentum-wheel, suitable power-transmitting connection between said wheel and said cam, said connection including a clutch, a pedal for driving said wheel, suitable connection whereby the pedal when at rest will hold said clutch open and thereby render the said power-transmitting connection inoperative, a weight or weighted connection whereby, when the pedal is depressed, the said clutch will automatically close and thereby communicate power and motion from said wheel to said cam, substantially as described.

12. The combination in a piano, of the hammers, a device for vibrating said hammers, a rotary momentum-wheel, a hub provided with dogs arranged to engage said wheel, a pedal, power-transmitting connection between said pedal and said hub, whereby the vibration of said pedal will operate to oscillate the said hub and thereby drive the said wheel, power-transmitting connection between said wheel and said device for vibrating the hammers, said last-mentioned power-transmitting connection including a clutch, and suitable connection between said clutch and said pedal whereby the latter can be employed for both rotating the wheel or discontinuing the transmission of power from the wheel to said cam, substantially as described.

13. In a piano the combination of the strings, means for vibrating the said strings, a rotary momentum-wheel for driving or operating the said means for vibrating the strings, a hub provided with dogs adapted and arranged to engage said wheel, a vibratory lever, a cord having one end attached to said lever and wound upon said hub and having its other end secured to a spring, said spring being secured to the body or frame structure of said piano, and a pedal connected and arranged for vibrating said lever, the vibratory motion of said lever operating to oscillate the said hub, and thereby rotate the said wheel, substantially as described.

14. The combination of a piano and an attachment therefor adapted and arranged for operating upon the strings of said piano, a rotary wheel having a suitable power-transmitting connection with said attachment for operating the strings of said piano, a hub provided with dogs adapted to engage said wheel, a cord wound upon said hub, and a pedal suitably connected with one end of said cord, the other end of said cord being secured, substantially as and for the purpose set forth.

696,475. SEWER DRAIN AND TRAP. CHARLES F. O'HILL, Paterson, N. J. Filed Sept. 20, 1901. Serial No. 75,701. (No model.)

Claim.—1. The combination of a suitable plate-like support having an opening therein, a trap disposed with one of its ends against the face of said support and surrounding the opening, a flanged ring-like frame or valve-seat having its flange disposed against the other face of said support, said trap and said frame or valve-seat being secured to the support each independently of the other, and a valve mounted in said valve-seat, substantially as described.

2. The combination of a suitable plate-like support having an opening therein, a trap disposed with one of its ends against the face of said support and surrounding the opening, a flanged ring-like frame or valve-seat penetrating said opening and having its flange disposed against the other face of said support, said trap and said frame or valve-seat being secured to the support each independently of the other, and a valve mounted in the end portion of said valve-seat which is indicated by the trap, substantially as described.

3. The combination of a suitable plate-like support having an opening therein formed with an extension, a trap disposed with one of its ends against the face of said support and around said opening, a flanged ring-like frame or valve-seat penetrating said opening and having its flange disposed against the other face of said support, said trap and said frame or valve-seat being secured in the support each independently of the other, legs projecting from said valve-seat through the extension of said opening, and a valve adapted to seat against said valve-seat and pivoted in said legs, substantially as described.

4. The combination of a suitable plate-like support having an open-

ing therein, a trap disposed with one of its ends against one face of said support and surrounding the opening, a flanged ring-like frame or valve-seat having its flange disposed against the other face of said support, said trap and said frame or valve-seat being secured to the support each independently of the other, a valve mounted in said valve-seat, and a guard or flange pivoted in said support above the ring and covering the latter, substantially as described.

696,476. FERTILIZER-DISTRIBUTER. CHARLES E. PALPUS, Springfield, Ohio. Filed Oct. 21, 1901. Serial No. 90,607. (No model.)

Claim.—1. In a fertilizer-distributor, the combination, with a box or hopper, of feeding device comprising a stationary hopper and feeding-shell, a rotary feed-plate, and stirring-arms secured to the wall of the feed-plate and extending upward therefrom into the box or hopper, said arms being bent or deflected so as to stand at an inclination to the wall to which they are attached, substantially as described.

2. In a fertilizer-distributor, the combination, with a box or hopper, of feeding device comprising a fixed bottom and feeding-shell, a rotary feed-plate, and stirring-arms secured to the wall of said feed-plate at an angle thereto, some of said arms extending inward over the feeding-shell, and others of said arms extending outward over the margin of the feed-plate, substantially as described.

3. In a fertilizer-distributor, the combination, with a box or hopper for containing the fertilizer, of feed-plates supported below the bottom of said box or hopper, hopper-shaped or inclined plates forming the bottom of said box or hopper and curving to conduct the fertilizer to said feed-plates, and stirring-arms attached to the wall of said feed-plates at an angle thereto, some of said arms extending inward over the hopper-shaped or inclined plates, substantially as described.

696,477. AUTOMOBILE. HOWARD J. PHILLIPS, London, England, assignor of one-half to J. W. Plank and George Edward Hill, Carlisle, Pa. Filed June 23, 1901. Serial No. 66,731. (No model.)

Claim.—1. In an automobile, the combination of driving-wheels, a swiveled fork-union for each driving-wheel, motor-cylinders forming parts of the fork and connected with said union, a crank-shaft having bearings in clearance of said cylinders, said shaft having cranks angularly arranged, a piston-rod and a cross-head for each cylinder, and connections between the cross-heads and the cranks, substantially as set forth.

2. In an automobile, the combination of driving-wheels, a swiveled fork-union for each driving-wheel, motor-cylinders forming parts of the fork and connected with said union, a crank-shaft having bearings in clearance of said cylinders, said shaft having cranks angularly arranged, a piston-rod and a cross-head for each cylinder, connections between the cross-heads and the cranks, and means for coupling up the several forks to a common steering-center, substantially as set forth.

ten-rod and a cross-head for each cylinder, connections between the cross-heads and the cranks, and steering device for said wheels, substantially as set forth.

3. In an automobile, the combination of driving-wheels, a swiveled fork-union for each driving-wheel, motor-cylinders forming parts of the fork and connected with said union, a crank-shaft having bearings in clearance of said cylinders, said shaft having cranks angularly arranged, a piston-rod and a cross-head for each cylinder, connections between the cross-heads and the cranks, and means for coupling up the several forks to a common steering-center, substantially as set forth.

696,478. CONDENSER FOR AUTOMOBILES. HOWARD J. PHILLIPS, London, England, assignor of one-half to J. W. Plank and George Edward Hill, Carlisle, Pa. Filed June 22, 1901. Serial No. 66,732. (No model.)

Claim.—1. In a device for effecting the condensation of exhaust-steam on steam road-vehicles, the combination with the steam-exhaust pipe, of a wheel, which is one of the running-wheels of the vehicle, said wheel having a chambered hub to receive the exhaust, and radially-arranged distributing-pipes leading from the chambered hub, said pipes being provided with discharge-openings near the rim, substantially as set forth.

2. In a device for effecting the condensation of exhaust-steam on steam road-vehicles, the combination with the steam-exhaust pipe, of a wheel which is one of the running-wheels of the vehicle, said wheel having a chambered hub to receive the exhaust, and radial hollow spokes extending from the chambered hub to the rim, said spokes being provided with discharge-openings near the rim, substantially as set forth.

3. In a device for effecting the condensation of exhaust-steam on road-vehicles, the combination with the steam-exhaust pipe of a chambered wheel, which is one of the running-wheels of the vehicle, a hollow axle upon which said wheel is mounted, there being communication between said chambered wheel and the interior of said axle, said wheel being provided with means for receiving, distributing and discharging the exhaust, substantially as set forth.

696,479. APPARATUS FOR TRIMMING COMMUTATORS. JOHN PHILLIPS, London, England. Filed Apr. 6, 1901. Serial No. 64,736. (No model.)

Claim.—1. In an apparatus for trimming commutators in position, a rotating trimming-wheel, a sliding carriage carrying the wheel, means for automatically traversing this sliding carriage and moving the wheel over the surface of the commutator, and driving mechanism actuated by the rotating commutator, having connections to the trimming-wheel and sliding carriage causing the wheel to revolve and the carriage to travel, substantially as herein described.

2. In an apparatus for trimming commutators in position, the combination with a rotating trimming-wheel, a sliding carriage supporting the trimming-wheel, adjustable slide in which the carriage can travel and means for effecting the traversing motion of the carriage and for stopping it at the required points, of driving apparatus actuated by the revolving commutator, connections between the driving apparatus and the trimming-wheel and connections with reducing-gearing between the driving mechanism and the sliding carriage, substantially as herein described.

3. In an apparatus of the kind described, a sliding carriage supporting the trimming-wheel and a rack upon the said carriage consisting of a screw having a portion of the thread removed throughout its length, adapted to engage with a revolving worm to give a traversing motion to the carriage and to be disengaged on turning, substantially as herein described.

4. In an apparatus of the kind described, the combination with a fixed support, a vertically-adjustable slide C, a sliding carriage E, trimming-wheel F upon the spindle F, screw-rack H, and worm-wheel J, of a driving-wheel O supported in the bearing M, pivoted arm N upon the fixed support and carrying the bearing M and connections from the driving-wheel to the trimming-wheel and to the worm-wheel, substantially as herein described and shown.

696,480. PORTABLE TUBULAR WELL AND TEST BORING MACHINE. CHARLES D. FISHER, Jersey City, N. J. Filed Oct. 17, 1901. Serial No. 74,968. (No model.)

Claim.—1. In a boring or drilling machine, the combination of a base having grooved ways in its upper part, a bed mounted to slide horizontally in said ways, the bed and base being provided with coincident cut-away portions, means for adjusting the bed with respect to the base, a plurality of standards carried by the bed and forming a vertical framework, and a ram movable vertically in said standards and in vertical line with the cut-away portion of the bed, substantially as set forth.

2. In a boring or drilling machine, the combination of a base having a cut-away portion and formed with ways in its upper part, a bed mounted in said ways and movable horizontally therein, said bed being provided with a cut-away portion coincident with the corresponding portion of the base, means for adjusting the bed with respect to the base, a plurality of standards carried by the bed and forming a vertical framework, a ram vertically movable in said standards in line with the cut-away portion of the bed, and a winch carried by and movable with the bed for operating the ram, substantially as set forth.

3. In a boring or drilling machine, the combination of a base, a bed adjustable horizontally with respect to said base, means for adjusting the bed, a plurality of standards removably carried by the bed and forming a

removable upright framework, a top plate removably carried by said standards at their upper end, a ram movable vertically in said standards, a winch carried by and adjustable with the bed, detachable connections between the winch and said ram, and a cam for detaching said connections adjustably mounted on and with respect to said standards, substantially as set forth.

696,481. ADDING-MACHINE. OLIVER H. PLATT, Cleveland, Ohio. Filed Jan. 2, 1901. Serial No. 62,182. (No model.)

Claim.—In recording-machines, (for mental calculations) the combination of the herein-described improvement, comprising the body A provided with series or rows of holes, to receive the key-stems 3, the bars B attached to the body A permitting of an oscillating movement of the bars, by means of the angular key-stems 3 and returning-spring 5, the spring 5 attached to pins 6, staples 4 attached to the body A, the angular key-stem 3 provided with the barrel 17 and key-top 2, the spring 4 actuating the angular key-stem 3 and key-top 2; for the purpose of constructing a recording-machine, wherein, by mechanically holding down keys after depression, a visible total (of mental addition) is recorded and shown by the keys on the keyboard of the machine all substantially as set forth.

696,482. REVERSE-LEVER. JOHN PLATT, Dunbart, N. Y., assignor to American Locomotive Company, New York, N. Y., a Corporation of New York. Filed July 22, 1901. Serial No. 69,578. (No model.)

Claim.—1. In a reverse-lever, the combination of an integral body, which is provided with a bearing-pin socket at its lower end, a reach-rod-pin socket located at one side of its upper end and projecting outwardly beyond the bearing-pin socket, and a lever-arm fixed to the upper end of the body, on the side thereof opposite the reach-rod-pin socket.

2. In a reverse-lever, the combination of an integral body, which is provided with a bearing-pin socket at its lower end, a reach-rod-pin socket located at one side of its upper end and projecting outwardly beyond the bearing-pin socket, and a lever-arm fixed to the opposite side of its upper end, and a lever-arm fitting the lever-arm seat, and secured thereto to the body.

3. In a reverse-lever, the combination of an integral body, which is provided with a bearing-pin socket at its lower end, a reach-rod-pin socket located at one side of its upper end and projecting outwardly beyond the bearing-pin socket, and a lever-arm fixed to the opposite side of its upper end, and a lever-arm fitting the lever-arm seat, and secured detachably to the body.

4. In a reverse-lever, the combination of an integral body, which is provided with a bearing-pin socket at its lower end, a reach-rod-pin socket located at one side of its upper end and projecting outwardly beyond the bearing-pin socket, and a laterally-flanged lever-arm fixed to the opposite side of its upper end, and a lever-arm fitting on the lever-arm seat and abutting on the lateral flanges thereof and secured detachably to the body.

5. In a reverse-lever, the combination of an integral cast-metal body, which is provided with a bearing-pin socket at its lower end, a reach-rod-pin socket located at one side of its upper end and projecting outwardly beyond the bearing-pin socket, a lever-arm fixed to the opposite side of its upper end, and strengthening edge flanges connecting its seats one with the other and with the lever-arm seat, and a lever-arm fixed to the body at the lever-arm seat.

6. In a reverse-lever, the combination of an integral plate reverse-lever body, which is provided with a bearing-pin socket at its lower end, a reach-rod-pin socket located at one side of its upper end and projecting outwardly beyond the bearing-pin socket, a bearing-pin secured to a fixed support and fitting the bearing-pin socket, and a lever-arm fixed to the upper end of the body on the side thereof opposite the bearing-pin socket.

696,488. GUIDE-YOKE BRACKET. JOHN FLAYER, Chicago, Ill. assignor to American Locomotive Company, New York, N. Y., a Corporation of New York. Filed Nov. 7, 1901. Serial No. 51,478. (No model.)

Claim.—1. An integral cast-metal guide-yoke bracket for locomotive guide-bars, having a substantially vertical body, an upper horizontal flange for attachment to an upper guide-bar, a lower horizontal flange for attachment to a lower guide-bar, and an upper vertical flange for attachment to a guide-yoke.

2. An integral cast-metal guide-yoke bracket for locomotive guide-bars, having a substantially vertical body, of channelled section, ribbed upper and lower horizontal flanges for attachment to an upper and a lower guide-bar, respectively, and a ribbed upper vertical flange for attachment to a guide-yoke.

3. In a locomotive engine, the combination of a guide-yoke secured to the boiler, upper and lower guide-bars, and guide-yoke brackets, each having an upper horizontal flange bolted to one of the upper guide-bars, a lower horizontal flange bolted to one of the lower guide-bars, and an upper vertical flange bolted to one side of the guide-yoke.

696,484. LOCOMOTIVE CYLINDER. JOHN FLAYER, Chicago, Ill. assignor to American Locomotive Company, New York, N. Y., a Corporation of New York. Filed Nov. 7, 1901. Serial No. 51,478. (No model.)

Claim.—1. A locomotive-cylinder middle-section in which are formed an upper bed-plate, a lower cylinder, a valve-chest communicating, by ports, with the ends of the cylinder, a steam-supply passage leading from the bed-plate to the central portion of the valve-chest, and exhaust-passages leading from the ends of the valve-chest to independent discharge-openings in the bed-plate.

2. A locomotive-cylinder middle-section in which are formed an upper bed-plate, a vertical inner web for connection to a counterpart middle-section, a cylinder located on the outer and lower portion of the section, a valve-chest communicating, by ports, with the ends of the cylinder, a steam-supply passage leading from the bed-plate to the central portion of the valve-chest, and exhaust-passages leading from the ends of the valve-chest to independent discharge-openings in the bed-plate located adjacent one to the other and to the inner web.

3. The combination of two locomotive-cylinder middle-sections, each having an upper bed-plate, a vertical inner web for connection to a counterpart middle-section, a cylinder located on the outer and lower portion of the section, a valve-chest communicating, by ports, with the ends of the cylinder, a steam-supply passage leading from the bed-plate to the central portion of the valve-chest, and exhaust-passages leading from the ends of the valve-chest to independent discharge-openings in the bed-plate, located adjacent one to the other and to the inner web, and an exhaust-pipe connected to the middle-section and having four lower openings, each communicating with one of the exhaust-passages discharge-openings.

696,485. LOCOMOTIVE ANTI-PAN. JOHN FLAYER, Chicago, Ill. assignor to American Locomotive Company, New York, N. Y., a Corporation of New York. Filed Nov. 7, 1901. Serial No. 51,477. (No model.)

Claim.—1. In a locomotive anti-pan, the combination of an upper section or body, a lower hopper or discharge-chute communicating therewith and having an inclined bottom provided with a discharge-opening, and a discharge-door suspended in position to be normally closed on the hopper-bottom by the action of gravity.

2. In a locomotive anti-pan, the combination of an upper section or body, a lower hopper or discharge-chute communicating therewith and having an inclined bottom provided with a discharge-opening, a discharge-door adapted to rest on the hopper-bottom and close the discharge-opening thereof, and swinging suspension-links supporting the discharge-door, and coupled thereto in position to permit it to be normally closed by gravity and to be opened by the application of an oppositely-acting force.

3. In a locomotive anti-pan, the combination of an upper section or body, a lower hopper or discharge-chute communicating therewith and having an inclined bottom provided with a discharge-opening, a discharge-door adapted to rest on the hopper-bottom and close the discharge-opening thereof, and swinging suspension-links pivoted at their upper ends to fixed supports and at their lower ends to the door, a vertical plate passing through the lower pivots intersecting the door, when closed, above the intersection therewith of a vertical plane passing through the upper pivots.

4. In a locomotive anti-pan, the combination of an upper section or body, a lower hopper or discharge-chute communicating therewith and having an inclined bottom provided with a discharge-opening, a discharge-door adapted to rest on the hopper-bottom and close the discharge-opening thereof, and swinging suspension-links pivoted at their upper ends to fixed supports and at their lower ends to the door, a vertical plate passing through the lower pivots intersecting the door, when closed, above the intersection therewith of a vertical plane passing through the upper pivots.

5. In a locomotive anti-pan, the combination of an upper section or body, a lower hopper or discharge-chute communicating therewith and having an inclined bottom provided with a discharge-opening, a discharge-door adapted to rest on the hopper-bottom and close the discharge-opening thereof, swinging suspension-links supporting the discharge-door and coupled thereto in position to permit it to be normally closed by gravity, an operating-shaft journaled transversely to the hopper, and a link connection coupling the discharge-door to an arm on the operating-shaft.

6. In a locomotive anti-pan, the combination of an upper section or body, two lower hoppers or discharge-chutes communicating therewith and having their bottoms provided with discharge-openings and inclined in relatively opposite directions, discharge-doors adapted to rest on the hopper-bottoms and close the discharge-openings thereof, pairs of swinging suspension-links, each of which supports one of the discharge-doors and is coupled thereto in position to permit it to be normally closed by gravity, and operating connections, having an interposed sliding or sliding bearing, through which opening movement is imparted to the discharge-doors.

7. In a locomotive anti-pan, the combination of an upper section or body, two lower hoppers or discharge-chutes communicating therewith and having their bottoms provided with discharge-openings and inclined in relatively opposite directions, discharge-doors adapted to rest on the hopper-bottoms and close the discharge-openings thereof, pairs of swinging suspension-links, each of which supports one of the discharge-doors and is coupled thereto in position to permit it to be normally closed by gravity, an operating-shaft journaled between and transversely to the hoppers, and connections coupling the discharge-doors to oppositely-projecting arms on the operating-shaft.

8. In a locomotive anti-pan, the combination of an upper section or body, two lower hoppers or discharge-chutes communicating therewith and having their bottoms provided with discharge-openings and inclined in relatively opposite directions, discharge-doors adapted to rest on the hopper-bottoms and close the discharge-openings thereof, pairs of swinging suspension-links, each of which supports one of the discharge-doors and is coupled thereto in position to permit it to be normally closed by gravity, an operating-shaft located between and transversely to the hoppers, an operating-shaft located between and transversely to the hoppers, and connections coupling the discharge-doors to oppositely-projecting arms on the operating-shaft.

pore, a fixed journal-bearing fitting one end of the operating-shaft, a movable journal-bearing fitting the opposite end of said shaft, and connections coupling the discharge-doors to oppositely-projecting arms on said shaft.

696,486. LOCOMOTIVE ANTI-PAN. JOHN FLAYER, Chicago, Ill. assignor to American Locomotive Company, New York, N. Y., a Corporation of New York. Filed Nov. 7, 1901. Serial No. 51,478. (No model.)

Claim.—1. In a locomotive anti-pan, the combination of a body which is open at its top and adapted to be connected thereto to a fire-box, a door or slide controlling a discharge-opening in the lower portion of the body, and a separator, forming a portion of the wall of the body adjacent to the top thereof, and provided with one or more air-admission passages having walls located in position to prevent the escape of solid matter.

2. In a locomotive anti-pan, the combination of a body which is open at its top and adapted to be connected thereto to a fire-box, a door or slide controlling a discharge-opening in the lower portion of the body, and a separator, forming a portion of the wall of the body adjacent to the top thereof, and provided with one or more inwardly and downwardly inclined air-admission passages.

3. In a locomotive anti-pan, the combination of a body which is open at its top and adapted to be connected thereto to a fire-box, a door or slide controlling a discharge-opening in the lower portion of the body, and a separator, forming a portion of the wall of the body adjacent to its top, said separator being inwardly and downwardly inclined and bent or corrugated transversely to form one or more air-admission passages.

696,487. BRUSH. ALBERT FULLER, Ash Grove, Mass. Filed Nov. 12, 1901. Serial No. 52,505. (No model.)

Claim.—1. A brush comprising a concave-convex body, provided around its front convex side with an integral marginal rim, having an inward edge, a plate within the body next to its convex face, a transparent flexible film over the plate, the plate and film being fixed over the said convex portion with their margins underlying and held down by the said inward edge of the rim; substantially as set forth.

2. The combination in a brush of the type described of a body convex upon the front and concave upon the back; a loop projecting from the back thereof and adapted to receive a pin; and a pin fixed rigidly upon said body by means of said loop so that said pin near its point bears firmly against the margin of said body upon the back thereof, substantially as described.

696,488. COMMUTATOR. EDWARD R. FRANK and GEORGE L. SCHREIBERMAN, Schenectady, N. Y., assignors to General Electric Company, a Corporation of New York. Filed Nov. 30, 1900. Serial No. 52,505. (No model.)

Claim.—1. A commutator built up of alternate strips of conducting and of heat-insulating material, the insulating material being of such a nature that it wears or tends to wear as fast as, or faster than, the conducting material.

2. A commutator for dynamo-electric machines, consisting of conducting-elements separated by soft insulating material which will wear or crumble away at least as fast as the segments.

3. A commutator for dynamo-electric machines, composed of alternate strips of copper, and of asbestos which will wear or crumble away at least as fast as the copper strips.

4. A commutator for dynamo-electric machines, consisting of conducting-elements separated by soft insulating material, and thin highly-insulating reinforcing-strips in connection with the insulating material.

5. A commutator for dynamo-electric machines, composed of conducting-elements separated by asbestos, with one or more thin mica strips reinforcing the asbestos.

6. A commutator for dynamo-electric machines composed of conducting-elements separated by asbestos, with a thin strip of mica on each side of each strip of asbestos.

7. A commutator comprising alternate conducting and insulating strips, the latter being of such nature that they will wear away at least as fast as the conducting-strips, and being treated with a water-repelling substance.

696,489. SEPARATOR FOR BATTERY-PLATES. JAMES E. PURCELL, Chicago, Ill. assignor to Western Storage Battery Company, Indianapolis, Ind., a Corporation of Indiana. Filed Apr. 2, 1901. Serial No. 52,502. (No model.)

Claim.—A separator for electric accumulators comprising a layer of inert, viscous material, adapted to be applied to the face of one of the plates of a battery, and a support for said layer consisting of two sheets of insulating material each having a series of parallel oblique slots placed at right angles and overlapping each other.

696,490. METAL AND RUBBER HOSE-ENDER. ARTHUR HENL, Akron, Ohio, assignor of one-third to Walter Frohmeyer, Akron, Ohio. Filed Jan. 12, 1902. Serial No. 52,500. (No model.)

Claim.—1. An improved hose-ender consisting of a thin metallic portion conformed to fit the hoof having around the inner edge of its lower face a raised rim inclined toward the central line of the shoe, an oppositely-disposed outer rim around the outer line of the shoe, heavier than the inner rim, said rim extending nearly to the heel, with curved cuts in said inner portion with the cut portions bent upward, a covering of rubber-laminate said metal portion excepting the heavy outer rim, and having integral rubber heel and toe collars, and a rubber-encased fabric covering integral rubber heel and toe collars, and a rubber-encased fabric covering

oring the upper face of said shoe, said parts being retained by the vulcanization of said rubber, substantially as shown and described.

8. An improved metal foundation for rubber harnesses consisting of a plate of metal of suitable configuration to fit the hoof having an integral metallic rim around the toe and sides about its outer line, a rim about its inner line inclined toward its center line, with curved cuts in the thin portion with the tongue thus produced bent slightly from the line of said portion, substantially as shown and described.

696,491. ELEVATOR FOR GINGER-PITS, JR. WILLIAM ROBERTSON, Chicago, Ill. Filed Mar. 21, 1901. Serial No. 68,188. (No model.)

Claim.—1. A car provided with a downwardly-operating bottom hinged at one end thereof, a plurality of rollers journaled centrally on said bottom and adapted to normally engage a supporting-rail acting to hold said bottom in a closed position.

2. A car comprising a bottom hinged at one end thereof, a plurality of rollers journaled centrally on said bottom and adapted to normally engage an immovable support acting to hold said bottom in a closed position.

3. In a device of the class described, the combination with a car having rigid side and end walls of a downwardly-opening bottom hinged at the rear end thereof, a plurality of rollers disposed on said bottom centrally and longitudinally thereof, a track on which the car is supported, a relatively short rail intermediate of the track-rail upon which said rollers engage and which acts to support said bottom in a closed position, a downwardly-curved portion at the rear extremity of the said intermediate rail at which point the bottom of said car opens and permits the contents of said car to slide outwardly.

4. The combination in a pit-elevator of an inclined track leading from the pit, a truck beneath the outer end of said inclined track adapted to support a receiving-car, an elevator-car movable along said inclined track, rigid side and end walls on said car, a downwardly-open bottom hinged at its rear end to the rear end of the car, an intermediate rail terminating in a downward end above the receiving-car, rollers disposed longitudinally on the bottom of the elevator-car and adapted to engage said intermediate rail, said rollers being so disposed that one or more of the same remain at all times in engagement with the intermediate rail and means for moving the elevator-car along its track to dumping position.

5. In a device of the class described, the combination with a railway cinder-pit of a transverse passage opening thereto, inclined track-rails extending transversely upwardly and outwardly from the cinder-pit, an elevator-car thereon, a bottom hinged at one end thereof, a downwardly-opening bottom hinged at the rear end of the car, rollers disposed longitudinally thereon, a relatively short rail located between said transverse track-rails and adapted normally to be engaged by said rollers and to support

said bottom in its closed position thereby, the outer end of said intermediate rail being downwardly curved, means operated by pneumatic pressure for moving the car outwardly and upwardly from the cinder-pit to a dumping position at the end of said intermediate rail at which point the bottom of said car drops downwardly with one of the rollers thereof still engaging said rail.

696,492. MANTLE-SUPPORT. JAMES I. ROBERT, Mount Vernon, N. Y. Filed Aug. 12, 1901. Serial No. 72,580. (No model.)

Claim.—The combination of a burner-cap of an incandescent gas-lamp, and a support for the mantle thereof, said support comprising a U-shaped part having one end fixed to said cap, a spring secured at one of its ends to the other end of the fixed part, and a second part for supporting the mantle at one end thereof, and having its other end connected with the other end of the spring.

696,493. MANTLE-SUPPORT. JAMES I. ROBERT, Mount Vernon, N. Y. Filed Aug. 12, 1901. Serial No. 72,510. (No model.)

Claim.—A mantle-support consisting of a pair of vertical rods, a support for one end of each rod, a band provided in each rod just above its support to have an inclined part, bands at the upper end of each rod to form a rest and a cross rod or bar from which the mantle is supported, removably supported on the rods of the vertical rods.

696,494. MACHINE FOR CLEANING AND RENOVATING FEATHERS. MARTIN E. ROBERT, Philadelphia, Pa. Filed June 14, 1901. Serial No. 64,622. (No model.)

Claim.—1. In a machine of the character stated, a tank, a spraying-blower therein, and means for supplying said blower with a cleaning or renovating agent, a blower-conveyor leading to an inlet-opening of said tank, a connection at the outlet-opening of said tank with said conveyor at the inlet end of the latter, and a blast-supply pipe, the latter and said connection having a common inlet in said blast-conveyor.

2. A machine of the character stated having a tank, a blower therein, a blast-conveyor and a feather-discharge pipe connected with opposite ends thereof, said discharge-pipe leading from said tank to said conveyor, and a blast-supply pipe, the latter and said discharge-pipe having a common inlet in said blast-conveyor, whereby feathers or other articles placed in the tank are blown in a circulating stream through the machine for drying purposes.

3. In a machine of the character stated, a tank, a blast-pipe, a chute containing said pipe and leading to the opposite end of said tank, and a discharge-pipe leading from said tank to said blast-pipe and connected therewith as an injector, said chute forming a common inlet for said blast and discharge pipes.

4. In a machine of the character stated, a tank, an air-blast conveyor connected with one end of said tank, a feather-discharge pipe connected with the other end of said tank, a blast-supply pipe, the latter and said discharge-pipe having a common entrance into said conveyor, and a drawer at the base of said conveyor.

696,495. METHOD OF PRESERVING EGGS. JORAN A. RYLANDER, Norrbyggen, Sweden. Filed Sept. 22, 1901. Serial No. 72,798. (No specimens.)

Claim.—A process for preserving eggs, which consists in first heating air saturated with methyl alcohol dissolved in alcohol to 80° centigrade.

inspecting the eggs to such air, and in applying a solution of potassium chloride previously heated at or about 80° centigrade when in a cooled state.

696,496. ACCUMULATOR. GEORGE DE ROBERT DE SALES and FRANKLIN GOSWAM, Lyons, France. Filed Mar. 12, 1901. Serial No. 61,012. (No model.)

Claim.—1. In an accumulator, a cathode consisting of a supporting-frame of aluminum covered with sheet-lead and lead covering the frame and extending therefrom in the form of a plate surrounded by the frame, an anode composed of an aluminum tank divided into compartments composed of the same metal, the interior of which tank is coated with lead so that each compartment forms the anode, two concentric or nested boxes having perforated walls separating the cathode from the anode and an absorbent material, substantially as described, arranged between adjacent walls of said boxes, said material adapted to absorb and to render the liquid electrolyte immovable, substantially as described.

2. In an accumulator, a cathode consisting of a supporting-frame of aluminum covered with sheet-lead and lead covering the frame and extending therefrom in the form of a plate surrounded by the frame and provided with metal wires forming a brush, an anode composed of an aluminum tank having a flange for its suspension divided into compartments composed of the same metal, the interior of which tank is coated with lead so that each compartment forms the anode, two concentric or nested boxes having perforated walls separating the cathode from the anode and an absorbent material, substantially as described, arranged between adjacent walls of said boxes, said material adapted to absorb and to render the liquid electrolyte immovable, substantially as described.

696,497. FUSE-BOX. HOWARD E. BARRETT, Schenectady, N. Y. Assignor to General Electric Company, a Corporation of New York. Filed Aug. 30, 1900. Serial No. 24,451. (No model.)

Claim.—1. The combination with the members B and C, of the ridges R, R', Q, Q', the terminals T and U and the faces F, F'.

2. The combination with two insulating-disks each formed with a depression and with a ridge in the depression, of means for holding the disks together so that the ridges register to form a partition having an opening, terminals on one disk on opposite sides of its ridge, a face connecting said terminals and passing through said opening, and terminals on the other disk which are connected with said terminals when the disks are held together.

3. The combination with two insulating-disks each formed with a depression and with a ridge, the ridge on one disk being formed with a groove, means for holding the disks together so that the ridges register to form a partition, terminals on one disk on opposite sides of its ridge, a face connecting said terminals and passing through the partition at the groove in said ridge, and terminals on the other disk which are connected with said terminals when the disks are held together.

4. The combination with two insulating members which together form a chamber, of two terminals mounted on one of said members, a face connecting said terminals, an integral insulating-partition formed by two ridges integral with the two insulating members, which divides said chamber into two parts, the face extending through the partition, and means for securing the two insulating members together.

5. The combination with two insulating members each formed with a depression, which together form a chamber, of two terminals mounted on one of said members, a face connecting said terminals, a ridge integral with each insulating member, so formed that when the members are

brought together to form a chamber, the ridges are located adjacent to each other to form a partition having an opening for the passage of the face, said partition dividing the chamber formed by the members into two parts, and terminals on the other disk which are connected with said terminals when the insulating members are held together.

6. The combination with two insulating members each formed with a depression which together form a chamber, of two terminals mounted on one of said members, a face connecting said terminals, a ridge integral with one of said members and formed with a groove for the reception of the face, a ridge integral with the other member, so located that when the members are assembled to form a chamber, the ridges will be adjacent to form a partition having an opening for the passage of the face, said partition dividing the chamber formed by the members into two parts, and terminals on the other disk which are connected with said terminals when the insulating members are held together.

7. In a contact device, the combination with an insulating-base and cover adapted to form a chamber, line-terminals in the base, terminals in the cover adapted to engage with those in the base, work-terminals in the cover, faces connecting the work-terminals with the other terminals in the cover, a ridge integral with the base, and a ridge integral with the cover, so located that when the base and cover are brought together to form a chamber located between the work-terminals and the other terminals of the cover, the ridges form a partition having an opening for the passage of the face, said partition dividing the chamber into two parts.

8. In a contact device, the combination with an insulating-base and cover adapted to form a chamber, line-terminals in the base, terminals in the cover adapted to engage with those in the base, work-terminals in the cover, faces connecting the work-terminals with the other terminals in the cover, a ridge integral with the base, and a ridge integral with the cover, so located that when the base and cover are brought together to form a chamber located between the work-terminals and the other terminals of the cover, the ridges form a partition having an opening for the passage of the face, said partition dividing the chamber into two parts.

9. In a contact device, the combination with an insulating-base and cover adapted to be brought together to form a chamber, of line-terminals on the base, terminals in the cover adapted to engage with those in the base, work-terminals in the cover, faces connecting the work-terminals with the other terminals in the cover, a ridge integral with the base, and a ridge integral with the cover, so located that when the base and cover are brought together to form a chamber located between the work-terminals and the other terminals in the cover, the ridges will form a partition having an opening through which the face extends, the chamber being divided into two parts by the partition.

10. In a contact device, the combination with an insulating-base and cover adapted to be brought together to form a chamber, of line-terminals on the base, contact-springs connected therewith, terminals in the cover adapted to engage said contact-springs to connect the cover-terminals with the line-terminals and secure the cover to the base, work-terminals in the cover, faces connecting the work-terminals with the other terminals connected to the spring-contacts, and an integral insulating-partition through which the face passes, the chamber formed by the base and cover being divided into two parts by the partition, and said partition being formed by two ridges integral with the base and cover.

11. In a contact device, the combination with an insulating-base and cover, of line-terminals on the base, terminals in the cover adapted to be connected with the line-terminals, work-terminals in the cover, faces connecting the work-terminals with the other cover-terminals, an integral insulating-partition between each work-terminal and one of the other cover-terminals of opposite polarity, integral insulating-partitions between the terminals which are connected by faces, openings being formed in the latter partitions for the reception of the faces, a hole in the top of the cover for the entrance of the branch-circuit wires, and passages from the work-terminals between the partitions to said hole for the reception of said wires.

12. The combination with two insulating members, each formed with corresponding depressions and with corresponding ridges in the depressions, two terminals being mounted on one of the insulating members on opposite sides of the ridge, and a face connecting said terminals, whereby when the insulating members are assembled, the terminals will be separated from each other by a partition formed by the ridges, and the portions of the face on opposite sides of the partition will be in chambers formed by the depressions in the insulating members.

696,498. CLOVER-BULLING ATTACHMENT FOR GRAM THRENNERS AND SEPARATORS. CHARLES SAYLER, Olathe, Mo. Filed Jan. 22, 1901. Serial No. 64,623. (No model.)

Claim.—1. A bulling-attachment comprising the head, base and

thereon, having their opposing sides rabbeted to form dovetail grooves between them, said bars being further provided on their opposing sides at one end with parallel-sided rabbets communicating with said grooves, teeth having dovetail cheeks adapted to enter said grooves by way of said rabbets, and keys to secure said teeth against movement longitudinally of the said bars, said keys engaging openings in cap of the heads, substantially as described.

2. In combination with a thrashing-machine and grain-elevator, a hulling attachment for clover and alfalfa, said hulling attachment comprising a cylinder and concave disposed in rear of the grain-chute, and immediately in advance of the tailings-conveyor, and a hinged valve above said hulling-cylinder to cover and uncover said hulling attachment, said valve when opened from said hulling-cylinder being disposed in rear of and below the grain-chute, and discharging into said hulling-cylinder, for the purpose set forth, and curving when closed to cover said hulling-cylinder and deflect material from the grain-chute into said hulling-cylinder and into said tailings-conveyor, substantially as described.

3. A hulling-cylinder comprising the heads, bars secured thereon, having their opposing sides rabbeted to form dovetail grooves between them, said bars being further provided on their opposing sides at one end with parallel-sided rabbets communicating with said grooves, teeth having dovetail cheeks in said grooves, rims on said cylinder, over said bars, and keys to secure said teeth in said grooves between said bars, said keys engaging openings in one of the heads and bearing against the outer side of one of said rims, substantially as described.

4. In a clover-huller, the combination of a toothed hulling-cylinder and a toothed concave on one side thereof, the teeth of said cylinder and concave being intercurrent, the lower rows of teeth on the concave being disposed more closely together than the upper rows of teeth thereof, substantially as described.

696,499. WAREHOUSE-TRUCK CARTER. THOMAS R. J. CARTER, Brooklyn, N. Y. Filed July 22, 1901. Serial No. 99,497. (No model.)

Claim.—1. In a warehouse-truck having notches in its forked sides, a center-wheel having the ends of its axle fitted in the said notches, and

cap-plates secured to the forked sides and provided with bearing-lugs to close the open ends of the notches and prevent displacement of the center-wheel, substantially as set forth.

2. In a center, a forked frame having its sides notched in their edges, a center-wheel having its journals fitted in the said notches, cap-plates having offsetting lugs to enter and close the open ends of the said notches, and means for adjustably connecting the cap-plates to the center-frame, substantially as set forth.

3. In combination, a forked center-frame, a center-wheel journaled in the fork members thereof, absorbent washers placed between the sides of the center-wheel and the adjacent sides of the fork members, cap-plates attached to the outer sides of the said fork members, and absorbent washers between the cap-plates and the fork sides, substantially as described.

4. In combination, a forked center-frame, a center-wheel journaled in the fork members thereof and having its journals extending through the outer faces of the said fork members, cap-plates attached to the fork members and recessed at their inner sides to form oil-chambers, the recesses being in communication with the bearings of the fork members for supplying lubricant thereto, and absorbent material in the said recesses and extending across the journal-bearings of the center-wheel, substantially as described.

5. In combination, a forked frame having its sides notched, a center-wheel having its journals fitted in the said notches, plates secured to the forked frame and having offsetting lugs to close the open ends of the notches and having recesses in their inner sides, and grooves in the ends of the said lugs in communication with the said recesses, substantially as set forth.

6. In combination, a forked frame having its sides notched, a center-wheel having its journals fitted in the said notches, absorbent material between the forked sides and center-wheel, cap-plates secured to the said forked sides and having bearing-lugs closing the open ends of the notches and grooved in their ends, said plates having their inner sides recessed, and absorbent material fitted in the recesses of the cap-plates, substantially as set forth.

696,500. APPARATUS FOR FIRE-FINISHING GLASSWARE. HENRY SHAW, Mount Pleasant, Pa. assignor to Bryco Brothers Company, Mount Pleasant, Pa., a Corporation of Pennsylvania. Filed Oct. 23, 1901. Serial No. 99,500. (No model.)

Claim.—1. In an apparatus for fire-finish glassware, the combination of a blowpipe-flame appliance, a traversing mechanism by which articles of glassware are successively presented to and withdrawn from the flame of said appliance, and a flame-paraffin interposed between said appliance and the wave-traversing mechanism.

2. In an apparatus for fire-finish glassware, the combination of a gas-supply pipe, an air-blast pipe, a flame-paraffin consisting of a body of refractory material having a tortuous channel or conduit with which the gas and air pipes are connected, a plurality of inclined deflecting-surfaces in said channel, and a wave-traversing mechanism located adjacent to the discharge end of said channel.

3. A flame-paraffin for fire-finish apparatus composed of an inclining cone or shell and a body of refractory material supported thereon and having formed within it a longitudinal channel or conduit provided with deflecting-surfaces which are presented by alternately oppositely inclined or curved portions of its walls.

696,501. LUBRICATING-CAR. JAMES SUMNER, Ladlow, Ky. Filed Dec. 17, 1901. Serial No. 99,501. (No model.)

Claim.—1. In a hand-tilt, the combination of an oil-reservoir, an outlet-spout with a discharge-valve, a valve to control such discharge, an inlet-opening, a fill-tube surrounding the same, a hollow screw-plug to close this latter having a hollow knob consisting of two sections on its upper side and a hollow central extension on its lower side which extends into the oil-reservoir, all these parts in open communication with each other, an air-inlet between the two sections of the hollow knob and an additional one in the lower pointed end of its central extension.

2. In a hand-tilt, the combination of an oil-reservoir, an outlet-spout with a discharge-valve, a valve to control such discharge, an inlet-opening, a fill-tube surrounding the same, a hollow screw-plug to close this latter and a hollow knob for its manipulation above the same and in open communication therewith, each knob being in two sections connected in a manner to permit access of air at the joint between them, thus providing the requisite air-vent.

3. In a hand-tilt, the combination of an oil-reservoir, a fill-tube for the same, a hinged outlet-spout, a valve-seat therein, a valve for it, a rocker-arm to which this valve is connected, a spring for keeping the valve normally seated, a rock-shaft for the rocker-arm, a shoulder 33 thereon, bearings to support this rock-shaft extending from opposite sides inwardly and with their inner ends in contact, one with the rocker-arm and the other with shoulder 33 whereby in conjunction with each rocker-arm and said shoulder the rock-shaft is longitudinally held in position between the opposite inner ends of its bearings and means to manipulate this rock-shaft.

4. In a hand-tilt, the combination of an oil-reservoir, a fill-tube for the same, a hinged outlet-spout, a valve-seat therein, a valve for it, a rocker-arm to which this valve is connected, a spring for keeping the valve normally seated, a rock-shaft for the rocker-arm, a bearing 31 to support the inner end of the rock-shaft, a tubular bearing 32 to support the outer end which projects beyond this bearing, a shoulder 33 on the rock-shaft and in contact with the inner end of bearing 32, there being a ground joint between these two parts and an operating-handle on the projecting part of the rock-shaft, the hub of which is in contact with the outer end of bearing 32, thereby holding the members forming the ground joint at the inner end of said bearing in contact with each other.

696,502. PICTURE-FRAME. EDWARD SHAW, New York, N. Y. Filed Aug. 7, 1900. Serial No. 99,502. (No model.)

Claim.—In a picture-frame, the combination with a rim for holding a picture and having a grooved flange, of a detachable cover resilient back adapted to engage said flange and be held therein by its resiliency, and a spring attached to said back to hold a picture against said rim.

696,503. FIRE-FINISHING GLASSWARE. WILLIAM SHAW, London, England. Filed Dec. 14, 1900. Serial No. 99,503. (No model.)

Claim.—In the construction of fire-finish glassware, a hollow shakedown frame of the general shape of an individual step composed of strips of tubing arranged parallel to the length of the step, in combination with cross-bands holding them all firmly together at the ends and

center, and a covering of concrete, plaster or other suitable material, the whole substantially as described with reference to Figs. 1 and 2.

696,504. REGULATING DEVICE FOR AIR-COMPRESSORS. HENRY C. SHAW, Westfield, N. J., and WILLIAM FRAZER, Boston, Pa. assignors to the Ingersoll-Sergeant Drill Company, New York, N. Y., a Corporation of West Virginia. Filed Feb. 28, 1901. Serial No. 99,504. (No model.)

Claim.—1. The combination with an air-compressor and a motor therefor and a governor for the latter, of speed-varying mechanism between the motor and the governor and means for controlling said mechanism by the pressure of the air delivered by the compressor, substantially as herein described.

2. The combination with an air-compressor and a motor therefor, of a motor-controlling governor, means for driving said governor by said motor consisting in part of speed-varying mechanism interposed between said motor and the governor, and means under the control of the air delivered by the compressor for operating said speed-varying mechanism, substantially as herein described.

3. The combination with an air-compressor and a steam-engine for driving the same, of a throttle-valve and rotary governor for said engine, means for driving said governor by said engine composed in part of speed-varying mechanism interposed between said engine and the governor, and means under the control of the air delivered by the compressor for operating said speed-varying mechanism, substantially as herein described.

4. The combination with an air-compressor and a motor therefor, of a motor-controlling governor, a speed-varying mechanism consisting of two expanding and contracting pulleys and a belt between them, means for driving one of said pulleys from the motor-shaft, means for driving the governor from the other of said pulleys and means for simultaneously expanding one and contracting the other of said pulleys under the control of the pressure of the air delivered by the compressor, substantially as herein described.

5. The combination with an air-compressor and a motor therefor, of a motor-controlling governor, a speed-varying mechanism consisting of two expanding and contracting pulleys and a belt between them, means for driving one of said pulleys from the motor-shaft, means for driving the governor from the other of said pulleys, levers for expanding and contracting said pulleys, a screw-spindle having right and left hand threads and

note thereon for actuating said levers, and means for turning said spindle in one direction or the other under the control of the air delivered by the compressor, substantially as herein described.

3. The combination with an air-compressor and a motor therefor and a governor for the latter, of speed-varying mechanism consisting of two expanding and contracting pulleys and a belt between them, means for driving one of said pulleys from the motor-shaft, means for driving the governor from the other of said pulleys, levers for expanding and contracting said pulleys, a screw-spindle having right and left hand threads and nuts thereon for operating said levers, a toothed wheel on said spindle, a lever fulcrumed on said spindle and two pawls carried by said lever for turning said wheel and spindle in opposite directions, means for operating said lever by the rotation of one of said pulleys, two pawl-disengaging levers fulcrumed on said spindle for disengaging said pawls, and means under the control of the pressure of the air delivered by the compressor for separately operating said disengaging-levers, substantially as herein described.

4. The combination with an air-compressor and a motor therefor and a governor for the latter, of speed-varying mechanism consisting of two expanding and contracting pulleys and a belt between them, means for driving one of said pulleys from the motor-shaft, means for driving the governor from the other of said pulleys, levers for expanding and contracting said pulleys, a screw-spindle having right and left hand threads and nuts thereon for operating said levers, a toothed wheel on said spindle, a lever fulcrumed on said spindle and two pawls carried by said lever for turning said wheel and spindle in opposite directions, means for operating said lever by the rotation of one of said pulleys, two pawl-disengaging levers fulcrumed on said spindle for disengaging said pawls, cylinders one for each of said disengaging-levers and pistons in said cylinders actuated by fluid-pressure from any source for operating said levers, pipes leading from said sources to each of said cylinders, and a valve for opening and closing one of said pipes under the control of the final pressure of the air delivered by the compressor, substantially as herein described.

5. The combination with a compound or multiple-stage compressor and a motor therefor and a governor for the latter, of speed-varying mechanism between the motor and the governor, means for operating the speed-varying mechanism by fluid-pressure from an intermediate receiver, and a valve under the control of the final-receiver pressure for admitting and shutting off the intermediate-receiver pressure from said means for operating the speed-varying mechanism, substantially as herein described.

696,505. HAY-DRESSER. HENRY C. SPARKS, Harris county, Pa. Filed Apr. 5, 1901. Serial No. 54,598. (No model.)

Claim.—1. A hay-dresser comprising a supporting-plate, a fixed base-ring thereon, a ring 20 on said base-ring, said ring 20 having a peripheral groove and a series of notches or grooves in said groove, a fixed ring 21, supported on said fixed base-ring, a wheel-ring 22 revolvable on said fixed ring 21, and having on said ring 22, said wheel-ring carrying a pulley 23, a sweep-lever pivotedly mounted on said supporting-plate, a detent pivoted to said sweep-lever and adapted to engage said wheel-ring and rotate the same with said sweep-lever and a bolt carried by said sweep-lever, to lock said detent to said ring-wheel, in combination with a holding-rope engaging the pulley 23 and having one end secured to a fixed point, substantially as described.

2. The combination of a support, a holding-rope, a revolvable element mounted on said support, adapted to draw on said rope, when said revolvable element is rotated, said revolvable element having radial members, a sweep-lever mounted on said support above and revolvable independently of said revolvable element, a gravity-detent pivoted at its upper end to and carried by said sweep-lever and adapted to drop and engage one of said radial members of said revolvable element to lock the latter to said sweep-lever, and a bolt also carried by said sweep-lever, to lock said detent when thus engaged, and to release said detent to permit retrograde rotation of said revolvable element, for the purpose set forth, substantially as described.

3. The combination of a support, a holding-rope, a revolvable element mounted on said support, adapted to draw on said rope, when said revolvable element is rotated, said revolvable element having radial members, a sweep-lever mounted on said support above and revolvable independently of said revolvable element, a gravity-detent pivoted at its upper end to and carried by said sweep-lever and adapted to drop and engage one of said radial members of said revolvable element to lock the latter to said sweep-lever, a bolt also carried by said sweep-lever, to lock said detent when thus engaged, and to release said detent to permit retrograde rotation of said revolvable element, for the purpose set forth, and a lever connected to said bolt, to release the latter from said detent, and a spring to normally maintain said bolt in engaged position with relation to said detent, substantially as described.

696,506. REWINDING APPARATUS. JOHN G. W. BRADLEY, London, England. Filed June 12, 1901. Serial No. 54,514. (No model.)

Claim.—1. In an apparatus for extracting oleaginous matter from fish, meat, &c., the combination of a closed vessel, a perforated plate extending transversely thereof above the bottom, a vertical partition extending upwardly from the perforated plate to form two compartments above the said plate communicating at one end of the partition, a perforated steam-pipe on each side of the partition to discharge free steam into the respective compartments, means to feed the material to be treated to the end of one compartment, means to move it through the compartments and maintain it in a broken-up condition, and means to drain off the oleaginous matter from the space between the perforated plate and the bottom of the vessel, substantially as set forth.

2. In an apparatus for extracting oleaginous matter from fish, meat, &c., the combination of a closed vessel, a perforated plate extending transversely thereof above the bottom, a vertical partition extending upwardly from the perforated plate to form two compartments above the said plate communicating at one end of the partition, a perforated steam-pipe on each side of the partition to discharge free steam into the respective compartments, means to feed the material to be treated to the end of one compartment, means to move it through the compartments and maintain it in a broken-up condition, and means to drain off the oleaginous matter from the space between the perforated plate and the bottom of the vessel, substantially as set forth.

3. In an apparatus for extracting oleaginous matter from fish, meat, &c., the combination of a closed vessel, a perforated plate extending transversely thereof above the bottom, a vertical partition extending upwardly from the perforated plate to form two compartments above the said plate communicating at one end of the partition, a perforated steam-pipe on each side of the partition to discharge free steam into the respective compartments, means to feed the material to be treated to the end of one compartment, means to move it through the compartments, means to discharge the cooked material, an exhaust-pipe leading from the closed vessel, and means to drain off the oleaginous matter from the space between the perforated plate and the bottom of the vessel, substantially as set forth.

4. In an apparatus for extracting oleaginous matter from fish, meat, &c., the combination of a closed vessel, a perforated plate extending transversely thereof above the bottom, a vertical partition extending upwardly from the said plate to form two compartments above the plate communicating at one end, means to admit free steam to each compartment, means to feed the material to be treated to the end of one compartment, and means to move it through the compartments and maintain it in a broken-up condition, substantially as set forth.

696,507. ALCOHOL-LAMP. GEORGE STERNES and LOREN BRUNSWICK, New York, N. Y., assignors to S. Sternes & Co., New York, N. Y., a Corporation. Filed Oct. 20, 1901. Serial No. 50,494. (No model.)

Claim.—1. In an alcohol-lamp, the combination of a fuel, a regulating-tube rigidly carried by the fuel, a burner movable toward and away from the fuel and movable toward and away from the regulating-tube, and means for moving said burner, substantially as set forth.

2. In an alcohol-lamp, the combination of a fuel, a regulating-tube rigidly carried by the fuel, a burner movable toward and away from the regulating-tube, a series of gas-vents at the top of the burner arranged to be covered by the downward movement of the burner in the regulating-tube, and means for moving said burner, substantially as set forth.

3. In an alcohol-lamp, the combination of a fuel, a regulating-tube rigidly carried by the fuel, a wick and burner tube movable within the regulating-tube, said wick and burner tube carrying an asbestos packing in its upper portion and a wick-like material in its lower portion which dips in the alcohol in the fuel, and means for moving said wick and burner tube, substantially as set forth.

4. In an alcohol-lamp, the combination of a fuel, a regulating-tube rigidly carried by the fuel, a wick and burner tube movable within the regulating-tube, said wick and burner tube carrying an asbestos packing in its upper portion and a wick-like material in its lower portion which dips in the alcohol in the fuel, means for moving said wick and burner tube, and a filling-tube mounted concentrically within the wick and burner tube, substantially as set forth.

5. In an alcohol-lamp, the combination of a fuel, a regulating-tube rigidly carried by the fuel, a wick and burner tube movable within the regulating-tube and communicating with the fuel, said wick and burner tube having burner-openings near its upper end arranged to be covered by the regulating-tube, a rack on the wick and burner tube within the regulating-tube, a pinion engaging said rack, and a shaft for rotating said pinion, substantially as set forth.

696,508. FIRE-ESCAPE. WILLIAM STEVENS, Albany, New South Wales, Australia. Filed Jan. 31, 1900. Serial No. 51,598. (No model.)

Claim.—1. In a fire-escape, a tube A open at its bottom and closed at its upper end, an air-regulating valve at said upper end, a weighted piston in said tube, an expansion-washer carried by said weight, and a rope or cable connected to said weight, substantially as described.

2. In a fire-escape, a tube A having an open lower end and a closed upper end, an air-regulating valve at said upper end, a weight in said tube connected at said upper end, a cup-shaped expansion washer seated in said conical end of the weight, and a rope or cable connected to said weight, substantially as described.

3. In a fire-escape, a tube A closed at its upper end and open at its lower end, a tapering weight within said tube having a conical upper end, a cup-shaped expansion-washer seated in said conicality, a clamping-disk within said washer, a bolt passing through said disk, washer and weight, for clamping them together, and a rope connected to said rod, substantially as described.

696,509. JOURNAL-BEARING. JAMES STICKEL, Williamsport, Pa., assignor of five-sixths to Henry C. McCornick and C. F. Overhiser, Williamsport, Pa., and Joseph L. Atkins, Washington, D. C. Filed Apr. 28, 1901. Serial No. 57,488. (No model.)

Claim.—1. In a journal-bearing, the combination with a box provided with cup-plates and a plurality of rolling bearing members contained within the box between the cup-plates thereof, of two series of rolling spacing members at opposite ends, respectively, of the bearing members, and a pair of loose clamping members for each series of spacing members carried by the spacing members within the box.

2. In a journal-bearing, the combination with a box provided with

cap-plates and a plurality of rolling bearing members contained within the box between the cap-plates thereof, there being reduced ends upon each of the bearing members, of a series of rolling spacing members for each end of the bearing members, and a pair of sliding members for each series of spacing members carried by the spacing members loose within the box.

3. In a journal-bearing, the combination with a box provided with cap-plates and a plurality of rolling bearing members contained within the box between the cap-plates thereof, said bearing members being shorter than the box, there being reduced ends upon each of the bearing members, of a series of rolling spacing members for each end of the bearing members making contact with the bearing members and with the cap-plates of the box, and a pair of loose sliding members for each series of spacing members carried by the spacing members within the box.

4. In a journal-bearing, the combination with a box provided with cap-plates and a plurality of rolling bearing members contained within the box between the cap-plates, said bearing members being shorter than the box, there being reduced ends defined, respectively, by shoulders upon each of the bearing members, of a series of rolling spacing members for each end of the bearing members, said spacing members making contact with the reduced ends and shoulders of the bearing members, and a pair of loose-sliding members for each series of spacing members carried by the spacing members within the box.

696,510. PICTURE-HANGER. CHARLES I. STELL, New York, N. Y. Filed Mar. 27, 1901. Serial No. 68,671. (No model.)

Claim.—1. In a picture-hanger, the combination with a central core or journal and means for attaching the core to the frame, of a spiral revolvably mounted on said core and having a ratchet on its face, a pawl pivoted to the journal or core and adapted to engage the ratchet to lock the spiral against movement in one direction, and also to lock the spiral upon the core, substantially as described.

2. In a picture-hanger, the combination with a central core provided with a roughened portion adapted to be pressed into the wood of the frame, means for securing the core to the frame, a spiral revolvably mounted on the core, a ratchet on the outer face of the spiral, a pawl pivoted to the core and adapted to engage the ratchet, whereby the spiral is locked against movement in one direction, and also locked upon the core, substantially as described.

3. In a picture-hanger, the combination with a core provided with a flange on its lower peripheral edge and having a screw integral therewith to attach it to the frame, of means for preventing the core from turning on the frame, a spiral revolvably mounted on the core and seated against the flange, a ratchet in the outer face of the spiral, and a pawl pivoted to the core and engaging the ratchet to lock the spiral against rotation in one direction and also to lock said spiral upon the core, substantially as described.

696,511. TRUCK-BOLSTER FOR RAILWAY-CARS. CHARLES H. STELL, New York, N. Y. Filed Dec. 1, 1902. Renewed Dec. 21, 1901. Serial No. 68,684. (No model.)

Claim.—1. The truck-bolster for railway-cars comprising in combination a center block or casting A, an upper compression member or bar B, a lower tension member or bar C having a head or flange e at each end, and a connecting or abutment block D having an upper web d' with a recess d therein and shoulder d' for the end of said bar B to seat against, and rivets passing through said web d' and bar B, and said block D being furnished with lower web d'' having a recess d'' and shoulder d'' for the head and/or flange e of the lower tension member or bar C to bear against, and a base block or casting F, between which and the connecting-block D said lower bar C is clamped, and connecting bolts or rivets, substantially as specified.

2. The truck-bolster for railway-cars comprising in combination a center block or casting A, an upper compression member or bar B, a lower tension member or bar C having a head or flange e at each end, and a connecting or abutment block D having a recess d and shoulder d' for the end of said bar B to seat against, and furnished with a recess d'' and shoulder d'' for the head and/or flange e of the lower tension member or bar C to bear against, and a base block or casting F between which and the connecting-block D said lower bar C is clamped, and connecting bolts or rivets, substantially as specified.

the connecting-block D said lower bar C is clamped, and connecting bolts or rivets, said block D having a recess d' to permit rivets to be inserted horizontally through the head or flange e of the bar C, substantially as specified.

3. The truck-bolster for railway-cars comprising in combination a center block or casting A, an upper compression member or bar B, a lower tension member or bar C having a head or flange e at each end, and a connecting or abutment block D having an upper web d' with recess d therein and shoulder d' for the end of said bar B to seat against, and rivets passing through said web d' and bar B, and said block D being furnished with lower web d'' having a recess d'' and shoulder d'' for the head and/or flange e of the lower tension member or bar C to bear against, substantially as specified.

4. The truck-bolster for railway-cars comprising in combination a center block or casting A, an upper compression member or bar B, a lower tension member or bar C having a head or flange e at each end, and a connecting or abutment block D having recess d and shoulder d' for the end of said bar B to seat against, and furnished with a recess d'' and shoulder d'' for the head and/or flange e of the lower tension member or bar C to bear against, said block D having an upper web d' through which the rivets pass to secure the bar B thereto, and a lower web d'' through which rivets pass to secure the bar C thereto, substantially as specified.

696,512. CIGAR-MONSTER AND PRESS AND BRAND TICKET. STEPHEN STRAUB, New York, N. Y. Filed Apr. 13, 1901. Serial No. 68,681. (No model.)

Claim.—1. The combination, with a cigar-monster, of a clamp-support adapted for attachment to a cigar-box and support the monster in the box, the clamp-support consisting of opposing clamping members adapted for engagement with opposite faces of a member of a box, a horizontal yoke located at the upper portion of one of the members of the clamp and adapted to extend within the box to which the clamp-support is applied, and arms arranged for engagement with the monster, which

arms are pivotally connected with the clamping-support and in their normal position are adapted to rest upon the said yoke, as set forth.

2. The combination, with a cigar-monster having a plain upper section and a recessed or perforated lower section connected with said upper section and an absorbent material between the two sections, of a clamp-support comprising an outer yoke, inner fingers parallel with the side portions of the outer yoke, the outer yoke and fingers having a downward direction, an inwardly-projecting horizontal yoke extending from the upper portion of the fingers, and arms pivotally attached to the upper portion of the clamp-support, which arms enter the monster through apertures in its edge, as set forth for the purpose specified.

3. In a cigar-monster, a monster proper, a clamp adapted to be secured to a cigar box and provided with an inwardly-projecting horizontal member, and arms pivotally connected with the clamp and to the free ends of which the monster is secured, said arms in their normal position being adapted to rest on the inwardly-projecting horizontal member of the clamp, as set forth.

4. In a cigar-monster, a monster proper, a clamp comprising an outer yoke, inner fingers parallel with the side portions of said yoke, and an inwardly-projecting horizontal yoke extending from the upper portion of the fingers, and arms pivotally connected with the upper portion of the clamp and adapted to rest upon the horizontal yoke when in their normal position, the free ends of the arms being adapted to be secured to the monster, as set forth.

696,513. DETACHABLE COUPLER. RICHARD M. GROSS, Kansas City, Mo., assignor to Stange Manufacturing Company, a Corporation of Missouri. Filed Apr. 1, 1901. Serial No. 68,682. (No model.)

Claim.—In a coupling for gas-jets, the combination with an exterior casing A, of an interior tubing B projecting within the said casing, a flexible tube C secured at one end to the interior of the casing A and the exterior of the tubing B, whereby this end of the flexible tube is prevented from direct engagement with the gas-jet that is to be coupled to permit of the ready removal and replacement of the tube, the other end of the said flexible tube projecting beyond the tubing and having space intervening between the same and the exterior casing, whereby it may readily grasp the gas-jet, the casing B being of larger diameter than the flexible tube to permit of the application of gas-pressure to the exterior of the tube to reinforce the engagement between the same and the gas-jet, and a connector D having communication with the interior of the casing A whereby gas passed through the jet and connection may have access to the space surrounding the tube to press the tube against the gas-jet, substantially as described.

696,514. HEATING APPARATUS. RICHARD M. GROSS, Kansas City, Mo., assignor to Stange Manufacturing Company, a Corporation of Missouri. Filed June 24, 1901. Serial No. 68,683. (No model.)

Claim.—1. In a heater, the combination with a gas-burner provided at one end with an unthreaded union adapted to be slipped over a gas-jet, the said burner being provided with an offset portion a, a vertical or upright stretch and a stretch irregularly disposed with respect to the vertical or upright stretch, the angular stretch being provided with a plurality of jet-openings arranged longitudinally thereof, of a heating-tube support adapted to secure the heating-tube in a longitudinal position with respect to the angular stretch of the gas-burner, and means for heating the upright and angular stretches of the gas-burner to prevent their displacement by the supported heating-tube, substantially as described.

2. In a heater, the combination with a gas-burner provided at one end with an unthreaded union adapted to be slipped over a gas-jet, the said burner being provided with an offset portion a, a vertical or upright stretch and a stretch irregularly disposed with respect to the vertical or upright stretch, the angular stretch being provided with a plurality of jet-openings arranged longitudinally thereof, of a heating-tube support adapted to secure the heating-tube in a longitudinal position with respect to the angular stretch of the gas-burner, and means for heating the upright and angular stretches of the gas-burner to prevent their displacement by the supported heating-tube, substantially as described.

heating-tube, the said end plates being separable, whereby the tongue of the heating-tube may engage an end plate and through the means of the said heating-tube and the angular stretch of the gas-burner to prevent the heating-tube from rotating or becoming disengaged from the engaging end plate, and means for preventing relative displacement between the vertical and horizontal stretches of the gas-burner, substantially as described.

3. The combination with a gas-burner provided with upright and angular stretches, the angular stretch being provided with longitudinally-arranged jet-openings, of a heating-tube support adapted to secure the heating-tube in a longitudinal position with respect to the angular stretch of the gas-burner, the said plates having free opening between them, whereby the heating-tube may be inserted between the end and tube to grasp an end plate and to secure the tube in an angular position, substantially as described.

4. The combination with a tube for receiving the tongue of a heating-tube, of a gas-burner spaced apart from said tube for directing a gas-flow against the said tube, and a plate P uniting the tube and gas-burner the space between the end and tube being free, whereby the heating-tube may be inserted between the end and tube to grasp the plate and secure the tube in an angular position, substantially as described.

696,515. PROCESS OF RETTING VEGETABLE FIBERS. BENJAMIN S. BROWN, Chicago, Ill. Filed Nov. 15, 1902. Serial No. 68,684. (No statement.)

Claim.—1. The herein-described process of retting vegetable fibers, which consists in subjecting the same to the action of an agent having an appetite or avidity for the ingredients sought to be removed, and having its solvent appetite or avidity for the ingredients, the presence of which lends quality and nature to the completed fiber, retted wholly or in part, whereby one class of ingredients is removed while the other remains intact, substantially as described.

2. The herein-described process of retting vegetable fibers, which consists in subjecting the same to an agent capable of removing the gummy constituent materials, and having its solvent avidity for the oily and waxy ingredients, which lend quality and nature to the completed fiber, retted wholly or in part, substantially as described.

3. The herein-described process of retting vegetable fibers which consists in subjecting the same to the action of a liquid having an avidity for the gummy constituent materials and having its solvent avidity for the ingredients of an oily or waxy nature which it is desired to retain in the completed fiber retted wholly or in part, substantially as described.

4. The herein-described process of retting vegetable fibers, which consists in subjecting the same to the action of water having its solvent avidity for the ingredients which it is desired to retain in the completed fiber retted wholly or in part, substantially as described.

5. The herein-described process of retting vegetable fibers, which consists in subjecting the same to the action of water having its solvent avidity for the ingredients of an oily and waxy nature which it is desired to retain in the completed fiber retted wholly or in part, substantially as described.

6. The herein-described process of retting vegetable fibers, which consists in subjecting an initial mass of the particular vegetable fiber to be retted to the action of the liquid which is to form the retting solution to saturate or impregnate the same with the oily and waxy ingredients and then subjecting the vegetable fibers to be retted to the action of said solution, substantially as described.

7. The herein-described process of retting vegetable fibers, which consists in subjecting an initial mass of the particular vegetable fiber to be retted to the action of the liquid which is to form the retting solution to remove the gummy material therefrom and to saturate or impregnate the same with the oily and waxy ingredients, subsequently extracting the gummy material from said liquid and leaving the same saturated or impregnated with the oily and waxy materials, and then subjecting the vegetable fibers to be retted to the action of this said solution, substantially as described.

8. The herein-described process of retting vegetable fibers, which consists in subjecting an initial mass of the particular vegetable fiber to be retted to the action of the liquid which is to form the retting solution to remove the gummy material therefrom and to saturate or impregnate the same with the oily and waxy materials, subsequently extracting the gummy material from said liquid and leaving the same saturated or impregnated with the oily and waxy materials, subjecting the vegetable fibers to be retted to the action of said solution, and, finally, removing the gummy material from said retting solution to render the same again active and permit the employment of the same in the further retting of vegetable fibers, substantially as described.

9. The herein-described process of retting an untreated retting solution containing gummy, oily and waxy ingredients active, which consists in subjecting the same to the action of an agent to precipitate the

gummy material while not affecting the city and waxy ingredients in the retting solution, substantially as described.

10. The herein-described process, which consists in subjecting a retting solution containing gummy material and city and waxy ingredients to the action of an agent capable of precipitating the gummy material without materially affecting the city and waxy ingredients, and then removing said agent and said precipitated gummy material from the solution, substantially as described.

11. The herein-described process, which consists in subjecting a retting solution containing gummy material and city and waxy ingredients to the action of an insoluble agent capable of precipitating the gummy material while not materially affecting the city and waxy ingredients and then removing said insoluble agent and said precipitated gummy material from the solution, substantially as described.

12. The herein-described process, which consists in subjecting a retting solution containing gummy material and city and waxy ingredients to the action of lead acid to precipitate the gummy material and then removing said lead acid and said precipitated gummy material from the solution, substantially as described.

13. The herein-described process, which consists in subjecting a retting solution containing gummy material and city and waxy ingredients, to the action of a practically insoluble agent capable of precipitating the gummy material while not materially affecting the city and waxy ingredients, removing the insoluble agent from the solution by mechanical operation and then removing the precipitated gummy material by filtration, substantially as described.

14. The herein-described method which consists in subjecting fibers of the kind to be retted to water to form the retting liquid, removing the gums from said liquid and then subjecting the fiber to be treated to the liquid thus formed to ret the same, substantially as described.

15. The herein-described method which consists in subjecting fibers of the kind to be retted to the action of water under heat and pressure as set forth to form the retting liquid, removing the gum therefrom, and then subjecting the fibers to be treated to the retting liquid thus formed under heat and pressure as set forth to ret the said fibers, substantially as described.

696,516. IMPROVED WINDOW FRAME. GASTON D. TARR, Newark, N. J., assignor to Tarr Window Company, Newark, N. J. Filed July 13, 1901. Serial No. 67,946. (No model.)

Claim.—1. The combination with the window-frame, the sash and the guide-bar arranged between the sash and frame, of a coupling having a pivotal connection with the sash and a fulcrum on said guide-bar, said

pivotal connection and fulcrum being arranged out of line with each other, substantially as set forth.

2. The combination with the window-frame, the sash and the guide-bar arranged between the sash and frame, of a coupling having a pivotal connection with the sash and having a fulcrum on said bar which is concentric to said pivotal connection, and means for rigidly connecting the sash and coupling or disconnecting the same, substantially as set forth.

3. The combination with the window-frame, the sash and a guide-bar arranged within the frame, of a guide-bar arranged between the sash and said guide, a pin pivotally connected with the sash, a head arranged on said pin and having a flat side which bears against a shoulder on the bar, and means for rigidly connecting the sash and pin or disconnecting the same, substantially as set forth.

4. The combination with the window-frame, the sash and the guide-bar arranged between the sash and frame, of a pin connected with the sash and passing through a curved slot in the bar, said pin being fulcrumed on one side on said bar concentric with the axis of said curved slot, substantially as set forth.

5. The combination with the window-frame, the sash and the guide-bar arranged between the sash and frame, of a pin arranged in a bearing on the sash and in a curved slot in said bar, a head arranged on said pin and fulcrumed on one side on a shoulder on the bar, said head being curved concentric with the fulcrum of said head, and a locking device for rigidly connecting the pin and sash or disconnecting the same, substantially as set forth.

6. The combination with the window-frame, the sash and the guide-bar arranged between the sash and frame, of a pin connected with the sash and arranged in a curved slot in said bar, a head arranged on the pin and adapted to fulcrum on the bar concentric with said slot, and a guide arranged on the bar for guiding said head out of said slot, substantially as set forth.

7. The combination with the window-frame, the sash and the guide-bar arranged between the sash and frame and having a longitudinal rib engaging with a corresponding groove in the sash, of a pin connected with the sash, a head arranged on the pin and fulcrumed on a shoulder on the bar, said pin being arranged in a slot which is formed partly in the guide-bar and partly in a plate on said bar and concentric with said fulcrum and having its lower end arranged adjacent to said shoulder and its outer end arranged in the rib of the bar, and a guide-bore arranged on said plate adjacent to the outer end of said slot for guiding said head out of said slot, substantially as set forth.

8. The combination with the window-frame, the sash and the guide-bar arranged between the frame and sash, of a pin pivotally connected with the sash and having a flat-sided stem at one end and a head at its opposite end which is fulcrumed on the guide-bar, and a locking-bolt guided on the sash and adapted to engage with the flat side of said stem, substantially as set forth.

9. The combination with the window-frame, the sash and the guide-bar arranged between the sash and frame, of a pin pivotally connected with the sash and having a flat-sided stem at one end and a head at its opposite end which is fulcrumed on the guide-bar, and a forked locking-bolt guided on the bar and adapted to engage with said stem for preventing turning of the sash on said pin, substantially as set forth.

10. The combination with the window-frame, the sash and the guide-bar arranged between the sash and frame, of a pin pivotally connected with the sash and having a head at one end which is fulcrumed on the guide-bar, a cylindrical stem arranged at the opposite end of the pin and having a circumferential groove and a flat side, and a forked locking-bolt guided on the sash and adapted to engage its arms with the groove and the flat side of said stem, substantially as set forth.

11. The combination with the window-frame, the sash and the guide-bar arranged between the sash and frame, of a pin pivotally connected with the sash and having a head at one end which is fulcrumed on the guide-bar and a flat-sided stem at its opposite end, and a forked locking-bolt guided on the sash and having a wide space between its arms in which said stem is capable of turning in the locking-bolt and a narrow space in which the stem is held against turning in the locking-bolt, substantially as set forth.

12. The combination with the window-frame, the sash and the supporting-bar pivotally connected with the sash, of a pressing device which is actuated by the weight of the sash and bar for pressing these parts together, substantially as set forth.

13. The combination with the window-frame, the sash and the guide-bar pivotally connected with the sash, of a balancing-chain or the like, and a pressing device which is actuated by the weight of the sash and guide-bar for yieldingly pressing these parts together, substantially as set forth.

14. The combination with the window-frame, the sash and the guide-bar pivotally connected with the sash, of a balancing-chain or the like connected with the guide-bar, and a pressing-lever which is interposed be-

tween the guide-bar and the frame and to which said chain is connected in a deflected condition, substantially as set forth.

15. The combination with the window-frame, the sash and the guide-bar pivotally connected with the sash, of a balancing-chain or the like connected with the guide-bar, and a pressing-lever bearing against the frame and bar and having a laterally-opening notch in which the chain is placed in a deflected condition, substantially as set forth.

16. The combination with the window-frame, the sash and the guide-bar pivotally connected with the sash, of a balancing-chain or the like connected with the guide-bar, a pressing-lever which bears against said frame and bar and to which said chain is attached in a deflected condition, and means for adjusting the amount of deflection in said chain, substantially as set forth.

17. The combination with the window-frame, the sash and the guide-bar pivotally connected with the sash, of a balancing-chain or the like connected with the guide-bar, a pressing-lever which bears against said frame and bar and which has an attaching-section to which a deflected portion of the chain is attached and an adjustable section for varying the amount of deflection in said chain, substantially as set forth.

18. The combination with the window-frame, the sash and the guide-bar pivotally connected with the sash, of a balancing-chain or the like connected with the guide-bar, a pressing-lever bearing against the frame and bar and consisting of an attaching-section which has a laterally-opening notch for receiving a deflected portion of the chain and an adjusting-section constructed to close said notch and to bear against said chain, substantially as set forth.

19. The combination with the window-frame, the sash and the guide-bar pivotally connected with the sash, of a balancing-chain or the like connected with the guide-bar, a pressing-lever bearing against the frame and guide-bar and consisting of an attaching-section which receives a deflected portion of said chain and an adjusting-section pivoted on the attaching-section and bearing against said chain, and an adjusting-curve arranged on the adjusting-section and bearing against an inclined stop on the attaching-section, substantially as set forth.

20. The combination with the window-frame, the sash and the guide-bar pivotally connected with the sash, of a balancing-chain or the like connected with the guide-bar, a pressing-lever bearing against the frame and guide-bar and consisting of an attaching-section and an adjusting-section, said attaching-section having upper and lower jaws forming a laterally-opening notch which received a deflected portion of said chain and said adjusting-section having a finger bearing against the chain, a curve bearing against an inclined stop in the upper side of said upper jaw and a retaining-leg bearing against the under side of said upper jaw, substantially as set forth.

21. The combination with the window-frame, the sash and the guide-bar pivotally connected with the sash, of a balancing-chain or the like connected with the guide-bar, a pressing-lever bearing against the frame and guide-bar and consisting of an attaching-section and an adjusting-section, said attaching-section having upper and lower jaws forming a laterally-opening notch in which a deflected portion of the chain is seated and an inclined stop on the upper side of the upper jaw, and said adjusting-section having a finger which bears against said chain, an adjusting-curve which bears against said inclined stop and a retaining-leg which bears against the under side of said upper jaw, and an anti-friction-roller arranged on said pin, substantially as set forth.

22. The combination with the window-frame, the sash and the guide-bar pivotally connected with the sash, of a catch arranged in the lower part of the guide-bar and consisting of a shank provided at its lower end with an upwardly-projecting hook and at its upper end with a cross-bar, a pair of guide-loops arranged on the guide-bar and receiving said cross-bar, and a shoulder arranged on the frame and adapted to be engaged by the hook of the catch, substantially as set forth.

23. The combination with a window-frame having a guideway, a shoulder in the back of said guideway, and an incline below said shoulder, of a guide-bar arranged in said guideway, a sash pivotally connected with said bar, and a catch mounted on the guide-bar and having a hook adapted to engage with the shoulder and the incline on the frame, substantially as set forth.

696,517. STRAIN-TRAP. WILLIAM E. THOMPSON and ROBERT THOMPSON, London, England. Filed June 14, 1901. Serial No. 64,000. (No model.)

Claim.—1. A steam-trap comprising essentially an expansion and contraction tube formed with a straight and a curved part, the curved part being capable of assuming a greater or less curve under varying temperatures due to the contraction and expansion of a spirit contained or sealed within the said tube, a casing carrying the one end of the curved part of the tube and enveloping the straight part thereof, an inlet and outlet provided on the said casing, a screen or strainer secured within said casing and through which the steam and water must pass before reaching the outlet, and a valve operated by the curved tube and controlling the said outlet, as set forth.

2. A steam-trap comprising essentially an expansion and contraction tube formed with a straight and a curved part, the curved part being capable of assuming a greater or less curve under varying temperatures due to the contraction and expansion of a spirit contained or sealed within the said tube, a casing carrying the one end of the curved part of the tube and enveloping the straight part thereof, an inlet and outlet provided on the said casing and a valve operated by the curved tube and the longitudinally expandible and contractible tube, controlling the outlet of the trap.

3. A steam-trap comprising a tube formed with a straight and a curved part, the curved part being capable of assuming a greater or less curve under varying temperatures due to the contraction and expansion of a spirit contained or sealed within the said tube, a casing carrying the one end of the curved part of the tube and enveloping the straight part thereof, an inlet and outlet provided on the said casing and a valve operated by the curved tube and controlling the said outlet, as set forth.

4. A steam-trap comprising a spirit-filled curved or spring tube carried on the outside of a casing and rigidly held by its one end and therein, a straight spirit-filled tube in communication with the curved or spring tube and carried and enveloped by the casing as to be in contact with the steam and water passing therethrough and a valve operated through mechanism attached to the free end of said curved tube to control the outlet of the trap, as set forth.

5. A steam-trap comprising a tube formed with a straight and a curved part, the curved part being capable of assuming a greater or less curve under varying temperatures due to the contraction and expansion of a spirit contained or sealed within the said tube, a casing carrying the one end of the curved part of the tube and enveloping the straight part thereof, an inlet and outlet provided on the said casing, a screen or strainer secured within said casing and through which the steam and water must pass before reaching the outlet, and a valve operated by the curved tube and controlling the said outlet, as set forth.

6. A steam-trap comprising a spirit-filled curved or spring tube carried on the outside of a casing and rigidly held by one end and therein, a straight spirit-filled tube in communication with the curved or spring tube and carried and enveloped by the casing as to be in contact with the steam and water passing therethrough and a valve operated through mechanism attached to the free end of said curved tube to control the outlet, as set forth.

7. A steam-trap comprising a spirit-filled curved or spring tube carried on the outside of a casing and rigidly held by one end and therein, a straight spirit-filled tube in communication with the curved or spring tube and carried within said casing, a longitudinally expandible and contractible

his tube carried by the said casing and carrying a valve-casing, and a valve operated through mechanism attached to the free end of said curved tube and connecting with said valve-casing to control the outlet of the trap, as set forth.

3. A steam-trap comprising a spirit-filled curved or spring tube carried on the outside of a casing and rigidly held by one end thereof, a straight spirit-filled tube in communication with the curved or spring tube and carried within said casing, a screen or strainer secured within the casing and through which the steam and water must pass before reaching the outlet, a longitudinally expandible and contractible tube carried by the said casing and carrying a valve-casing, and a valve operated through mechanism attached to the free end of said curved tube and connecting with said valve-casing to control the outlet of the trap, as set forth.

4. A steam-trap comprising a curved spirit-filled tube carried on the outside of a casing and rigidly held by its one end thereof, a straight spirit-filled tube in communication with the curved or spring tube and carried within the said casing, an inlet and an outlet provided on the said casing, a longitudinally expandible and contractible tube carried by the said casing, a screen or strainer secured within the casing and through which the water must pass before reaching the outlet, a blow-off cock communicating with the compartment formed by the screen or strainer, a valve-casing carried by the longitudinally expandible and contractible tube, a valve operated through mechanism attached to the free end of the curved tube and connecting with the said valve-casing to control the outlet, and means for bringing the valve into proper working relation with respect to its casing, as set forth.

696,518. GAS OR OIL ENGINE. RAYMOND TOWNSEND, Southampton, Mass. Filed June 14, 1906. Serial No. 720,910. (No model.)

Claim.—1. In a gas or oil engine, the combination of two cylinders, spaces connected by a narrowed passage and traversed each by a piston connected to the main crank by suitable crank-arms and connecting mechanism; exhaust-ports opening from one of the cylinders, which may be called the main cylinder, and said ports uncovered or opened for expulsion of exhaust at or about the completion of the outward stroke of the piston within said cylinder; two ports or sets of openings in the second cylinder, one of which is for the passage of air under slight compression for conveying or washing out the exhaust charge, and the other of which when opened after the exhaust-ports are closed introduces a fuel charge under compression, substantially as described.

2. In a fuel or gas engine, the combination of two cylinders, a piston for each cylinder, which pistons are operatively connected to furnish power, means for exhausting one cylinder on the completion of the power-stroke, and means for introducing a body of air into the second cylinder on the completion of the power-stroke; means for cutting off the exhaust from the first cylinder, and means for introducing into the second cylinder a new charge of fuel and air, and a connection or port between the two cylinders, substantially as described.

3. In an oil or gas engine, the combination of two cylinders in communication through a narrowed part, pistons moving within said cylinders, cranks and connecting-rods for moving the pistons, one crank being set so as to have a lead over the other; exhaust-ports in the forward end of one cylinder uncovered by the piston on the completion of its stroke, and two ports or sets of ports in the other cylinder, and means for injecting air through the first open port or set of ports, with means for injecting the fuel charge through the second port or set of ports after the exhaust-ports of the engine are closed.

4. In an oil or gas engine, a crank-case including the main crank, a space in which air is compressed during the motion of the main piston, ducts or delivery-ports extending from said crank-case for delivering air to the working cylinder-spaces, a piston moving within the main cylinder arranged to uncover the exhaust-ports on the completion of its outward stroke, an oppositely-moving piston arranged to uncover successively a port or set of ports for introducing air, and another set of ports for introducing the fuel charge into the explosion-chamber; means for moving the two pistons respectively; means for taking in and compressing the fuel

charge, and means such as an oil-supply pipe and an air-dust for supplying fuel and air for their admission before they pass the fuel-ports leading to the explosion-chamber, substantially as described.

5. In an oil or gas engine, the combination of a piston, which is moved within the crank-case, compresses a charge of air, an exhaust-port which is uncovered at the end of the piston-stroke, a second piston moving oppositely to the first and lagging with respect thereto, a port communicating with the crank-case which is uncovered by the lagging piston during the interval that the exhaust-port is open, so that the burned gases are expelled, a fuel-port, also controlled by the lagging piston, for admitting fuel after the exhaust-port is closed, and means for introducing and mixing the fuel charge and transferring it from one side to the other of the lagging piston.

6. In a two-cycle engine, the combination of a cylinder-space, a pair of pistons working therein and connected to the same crank, one of said pistons acting on its outward stroke to compress a charge of air, the other to compress a charge of gas or fuel, ports controlled by the gas-compressing piston for admitting a charge of air composed by the first piston to the space between the pistons for discharging the burned gases and supplying air to a new charge, and other ports also controlled by the same piston for admitting the fuel charge to the cylinder-space.

7. In a two-cycle gas or fuel engine, the combination of two cylinder-spaces in communication through a port or restricted neck, each cylinder having a piston, means for exhausting the burned gases at one side of the restricted neck and from one end of the combined cylinder-space near its greatest volume, owing to the motion of the pistons, means for inserting a new charge of air close to the cylinder-spaces on the other side of the restricted neck, and means for subsequently inserting the fuel-charge.

8. In a gas or oil engine, the combination of a pair of pistons, a cylinder for each piston, a body of metal uniting the cylinders which is provided with a restricted neck or port, a firing means mounted adjacent to said body, an exhaust-ports controlled by one of the pistons, a port admitting air to the cylinder at or near the restricted neck, and a fuel-admitting port located beyond the air-admitting port, the last two ports being controlled by the second piston.

9. In a gas or oil engine, the combination of a cylinder, a piston therefor which compresses a charge of air on its outward stroke, a second piston which compresses a charge of fuel on its outward stroke, means for admitting fuel and compressed air to the compression-chamber, ports for admitting a charge of air to the chamber, ports for admitting a charge of air to the cylinder-space between the incoming fuel charge and the exhaust, and means for transferring the fuel from one side of the second piston to the other.

10. In an oil or gas engine, the combination of separate pistons which are operatively connected to the same power-shaft, a crank-case in which air is compressed by one piston, a case in which fuel is compressed by the end of a second piston, a port for admitting the compressed air into a space between the pistons, and means for transferring the compressed fuel charge from the end of one piston to a point between the pistons.

11. In a gas or oil engine, the combination of a pair of oppositely-moving pistons which are connected to the same driving-shaft, one of said pistons being arranged to lag slightly with respect to the other, a crank-case in which the air is slightly compressed by the leading piston, an exhaust-ports which is uncovered by the leading piston, a chamber in which the fuel is slightly compressed by the lagging piston, a port which is uncovered by the lagging piston for admitting the air compressed by the leading piston to the space between the pistons, a second port, also uncovered by the lagging piston, for permitting the fuel charge to be transferred to a point between the pistons after the leading piston has closed the exhaust-ports, and means for firing the fuel charge.

12. In a gas or oil engine, the combination of a moving piston, a crank-case in which the piston compresses a charge of air, a screen of fuel-supply, a port for admitting the compressed air into the cylinder for the purpose of washing out the products of combustion, which port is controlled by the movement of a piston, and a second port or valve for controlling the admission of the fuel charge, and a valve for regulating the air which is received from the crank-case and mixes with the fuel charge.

696,519. TABLE-JOINT. BENJAMIN T. TOWN, Hastings, Mass. Original application filed Feb. 13, 1901, Serial No. 47,740. Revised and this application filed May 10, 1901. Serial No. 60,515. (No model.)

Claim.—1. In a table, a leg having a shank at its upper end, and an element made rigid with the table having a lateral seat to receive the leg-shank; said element and leg-shank having, one, a base transverse to the axis of the leg-shank, and the other, a recess adapted to receive the base, the base being tapered in section radial to the shank—widening from its base to its outer end—means for clamping the shank into its seat and thereby forcing the tapering base into the recess.

2. In a table, a leg having a shank at its upper end, and an element made rigid with the table having a lateral seat to receive the leg-shank; said element and leg-shank having, one, a base transverse to the axis of the leg-shank, and the other, a recess adapted to receive the base, the base being tapered in section radial to the shank—widening from its base to its outer end—means for clamping the shank into its seat and thereby forcing the tapering base into the recess.

3. In a table, a leg having a shank at its upper end, and an element made rigid with the table having a lateral seat to receive the leg-shank; said element and leg-shank having, one, a base transverse to the axis of the shank, and the other a recess adapted to be engaged by the base; one of said engaged pieces being tapered in width to cause a wedging action in such engagement, and means for clamping the shank into its seat and thereby wedging the base into the recess.

4. In combination with a table-top and its legs, a block which is made rigid with the top, having in one edge a main recess, a leg having a shank adapted to be seated laterally in the recess; the shank having a base or head projecting transversely to the axis of the shank, and tapering in radial section, widening from base to crest, and the block having a secondary recess in the wall of the main recess, adapted to receive the base, and means for clamping the shank into the main recess and thereby forcing the base into the secondary recess.

5. In combination with a table-top and its legs, a block which is made rigid with the top, having in one edge a main recess; a leg having a shank adapted to be seated laterally in the recess; the shank having a base or head projecting transversely to the axis of the shank, and the block having a corresponding secondary recess in the wall of the main recess; and means for clamping the shank into the main recess, thereby forcing the base or head into the secondary recess.

6. In combination with a table-top and its legs, a block which is made rigid with the table-top independently of the leg, each block having in one edge a main recess; the leg having a shank adapted to be seated laterally in the recess, the shank having a base or head projecting transversely to its axis, and the block having a corresponding secondary recess in the wall of the main recess, and means for clamping the shank into the recess and thereby forcing the base or head into the secondary recess.

7. In combination with a table-top and its legs, a block which is made rigid with the table-top, having in one edge a main recess; a leg having a shank adapted to be seated laterally in the recess; the shank having a base or head projecting transversely to its axis, and the block having a corresponding secondary recess in the wall of the main recess, the face of the head toward the shoulder being beveled to draw the shoulder toward the face of the block when the shank is forced into the recess, and suitable means for thus forcing and holding the shank into the recess.

8. In combination with a table-top and its legs, a block which is made rigid with the table-top, having in one edge a main recess; a leg having a shank adapted to be seated laterally in the recess; the shank having a base or head projecting transversely to its axis, and the block having a corresponding secondary recess in the wall of the main recess, adapted to receive the base, one face of the base being beveled and the other being flat, and the width of the base at the base being such with respect to the width of the secondary recess as to cause the base to be wedged in the secondary recess when the shank is forced back into the main recess, whereby the flat face of the base is caused to be seated firmly against the corresponding wall of the recess; and suitable means for clamping the shank into the main recess.

696,520. FINGER-POPE. EDWARD T. VAN VALKENBURG, Ipswich, Ind., assignor of one-half to William E. Crutcher, Laporte, Ind. Filed May 13, 1906. Serial No. 62,401. (No model.)

Claim.—1. In an actuating device for wire frames, comprising an upright post, the horizontal base portion of right angles to the upright portion, inclined wire-braces connecting the corner-ports and the base portion, said inclined braces having contiguous clamping-ends for the wire frame, and anchoring device, substantially as described.

2. In an anchoring device for wire frames the combination with an upright post and the horizontal base portion formed of a single piece of metal, inclined brace-braces connecting the post and the base portions, a longitudinal slot formed on the face of one of said inclined braces, and an

anchoring longitudinal groove formed on the contiguous face of the other to clamp the wire frame between the two inclined braces, and anchoring device, substantially as described.

696,521. BRACK-ADJUSTER FOR BRAKES. EMERY A. WALKER, St. Louis, Mo., assignor to the American Brake Company, St. Louis, Mo., a Corporation of Missouri. Filed Aug. 1, 1901. Serial No. 70,708. (No model.)

Claim.—1. In a brake shank-adjuster, the combination with a shank-adjuster driven screw and a movable fulcrum-block, of a closed casing including said screw and means for operating the shank.

2. In a brake shank-adjuster, the combination with a shank-adjuster driven screw and a movable fulcrum-block, of a closed casing forming a guide for said fulcrum-block, and means for operating the shank.

3. In a brake shank-adjuster, the combination with a screw and a movable fulcrum-block, of a closed casing therefor, a shank-adjuster having a hollow extension for said screw, and means for operating the shank.

4. In a brake shank-adjuster, the combination with a shank-adjuster driven screw, of a cover or casing for enclosing the shank and a take-up motor supported on the shank casing or cover.

5. In a brake shank-adjuster, the combination with a movable fulcrum-block and shank-adjuster driven screw, of a casing forming a guide for the fulcrum-block, a shank-adjuster secured to the casing, and a take-up motor supported on the shank-adjuster.

6. In a brake shank-adjuster, the combination with a screw and a movable fulcrum-block, of a casing therefor having an elongated opening for a lever, and means for sliding the opening.

7. In a brake shank-adjuster, the combination of a movable fulcrum-block, a screw, a casing for the fulcrum-block having an elongated opening in one side for a lever, and a slide for sliding the opening.

8. A shank-adjuster comprising a movable fulcrum-block and screw, a casing therefor having a slot in one side for a lever, and a dust-plate secured to the movable fulcrum-block for closing said slot.

9. In a brake shank-adjuster, the combination with a take-up mechanism and a casing therefor, of a take-up motor supported thereon and adapted to be adjusted to any one of a plurality of positions.

10. In a brake shank-adjuster, the combination with a casing including a movable fulcrum-block and a shank-adjuster driven screw, of a cover for the shank-adjuster carrying a take-up motor, said cover being adjustable to any one of a plurality of positions with respect to the casing.

11. In a brake shank-adjuster, the combination with a casing including a movable fulcrum-block and screw and having an opening in one side for a lever, a dust-plate for said opening, and a shank-adjuster having a plurality of narrow slots and adapted to be adjusted to different positions whereby the dust-plate may extend through any one of said slots.

12. In a brake shank-adjuster, the combination with a shank-adjuster driven screw, of a take-up motor having a piston and piston-rod, and a pawl pivoted to the piston-rod and adapted to engage said shank.

13. In a brake shank-adjuster, the combination with a pawl and shank-adjuster mechanism, of a take-up motor having a piston and piston-rod, the pawl being pivoted to the piston-rod, and means for sliding the pawl

out of engagement with the ratchet when the piston is at one end of its traverse.

14. In a brake slack-adjuster, the combination with a pawl-and-ratchet mechanism, of a take-up motor having a piston and stem connected to the pawl, means for raising the pawl out of engagement with the ratchet when the piston is at one end of its traverse, and a spring for throwing the pawl into engagement with the ratchet when the piston is moved toward the opposite end of its traverse.

15. In a brake slack-adjuster, the combination with a movable filarum-block and ratchet-driven screw, of a guide for said movable filarum-block and a fixed filarum carried by said guide.

16. In a brake slack-adjuster, the combination with a movable filarum-block and ratchet-driven screw, of a casing therefor, a fixed filarum-block secured to said casing and means for securing the casing to a support.

17. In a brake slack-adjuster, the combination of a movable filarum-block, an adjusting-lever pivoted thereto, a ratchet-driven screw for moving said movable filarum, a stationary filarum, another adjusting-lever pivoted thereto, and a link connecting said levers together, the levers also being connected to sections of a pull-rod of the brake-rigging.

18. In a brake slack-adjuster, a brake-cylinder having a supporting-flange, an opening formed in the flange tangentially to the cylinder, a small port connecting the said opening with the interior of the brake-cylinder, and a pressure-pipe connected in said opening for conducting air under pressure to the take-up motor.

19. In a brake slack-adjuster, a brake-cylinder having a projecting flange or lug, an opening formed in said flange tangentially to the cylinder for a pipe connection, and a port connecting said opening with the interior of the brake-cylinder.

696,522. BRAKE SLACK-ADJUSTER. HENRY A. WALKER, St. Louis, Mo., assignor to the American Brake Company, St. Louis, Mo., a Corporation of Missouri. Filed Aug. 3, 1901. Serial No. 70,784. (No model.)

Claim.—1. In a brake slack-adjuster, the combination with a brake-cylinder head having a support secured thereto, of a tubular adjusting-screw rotatably mounted upon said support, said screw having a ratchet-wheel and a threaded filarum-block.

2. In a brake slack-adjuster, the combination with a tubular adjusting-screw and a support on which said screw is rotatably mounted adapted to be secured to the head of the brake-cylinder, of a threaded filarum-block, a ratchet-wheel secured to said screw and means for operating said ratchet-wheel.

3. In a brake slack-adjuster, the combination with a cylindrical support adapted to be secured to the head of a brake-cylinder, of a tubular adjusting-screw secured upon said support and having a ratchet-wheel and a threaded filarum-block.

4. In a brake slack-adjuster, the combination with an externally-threaded hollow screw, a movable filarum-block and a ratchet device for operating said screw, of a support extending into the hollow screw, and means for operating the ratchet.

5. In a brake slack-adjuster, the combination with a hollow adjusting-screw and a ratchet for operating the same, of a relatively movable filarum-block, and a support on which said screw is rotatably mounted.

6. In a brake slack-adjuster, the combination with a brake-cylinder head having a support extending therefrom, of a hollow adjusting-screw secured upon said support and having a movable filarum-block and a ratchet device for operating said screw.

696,528. BRAKE SLACK-ADJUSTER. HENRY A. WALKER, St. Louis, Mo., assignor to the American Brake Company, St. Louis, Mo., a Corporation of Missouri. Filed Aug. 3, 1901. Serial No. 70,786. (No model.)

Claim.—1. The combination of a brake-cylinder, a port therein adapted to be connected with a take-up motor of a slack-adjusting mechanism, a valve for normally closing said port and means operated by the

brake-cylinder piston for opening said valve when the piston traverses beyond a certain point.

2. The combination with a brake-cylinder head having a port therein adapted to be connected with a take-up motor of a slack-adjusting mechanism, of a valve for normally closing said port and means operated by the brake-piston for opening said valve.

3. In a brake-cylinder, the combination with the cylinder-head having a hollow extension and a port therein, communicating with the take-up motor of a slack-adjusting mechanism, of a slide-valve for normally closing said port and means operated by the brake-piston when it passes a certain point of its traverse for opening said valve.

4. In a brake-cylinder, the combination with the cylinder-head having a port communicating with the take-up motor of a slack-adjusting mechanism, of a valve for normally closing said port, and a valve-stem connected to the piston for opening said valve at a certain point in the traverse of the piston.

5. In a brake-cylinder, the combination with the cylinder-head having a port communicating with the take-up motor of a slack-adjusting mechanism, of a valve for normally closing said port, a valve-stem for the valve, a piston having a hollow rod into which the valve-stem extends, and a plate secured at the end of the hollow rod for moving the valve when the piston passes a certain point of its traverse.

6. The combination of a brake-cylinder, a take-up motor of a slack-adjusting device, a passage from the brake-cylinder to the take-up motor, a valve for normally closing said passage and means operated by the movement of the brake-piston for controlling said passage.

696,524. SLACK-ADJUSTER FOR RAILWAY-BRAKES. HENRY A. WALKER, St. Louis, Mo., assignor to the American Brake Company, St. Louis, Mo., a Corporation of Missouri. Filed Aug. 3, 1901. Serial No. 70,788. (No model.)

Claim.—1. In a brake-rigging, the combination with a main brake-operating lever having a fixed filarum, of an adjusting-lever having a movable filarum-block, a take-up mechanism for adjusting the position of the filarum-block, a pull-rod connected to the adjusting-lever, and a link connecting the main operating-lever with the adjusting-lever.

2. In a brake-rigging, the combination with an adjusting-lever pivoted to a movable filarum and a take-up mechanism for adjusting the position of said filarum, of a pull-rod connected to the adjusting-lever at one point, another member of the brake-rigging connected to the adjusting-lever at a different distance from its filarum, and a main brake-lever having a fixed filarum for operating one of said members.

3. In a brake-rigging, the combination of a brake-cylinder, a main brake-lever, an adjusting-lever having a fixed filarum, a movable filarum-block for the adjusting-lever, a pull-rod connected to one end of the adjusting-lever, a link connecting the main brake-lever with an intermediate point of the adjusting-lever, and a take-up mechanism for adjusting the position of the movable filarum-block.

696,524.

696,526. LOCOMOTIVE-BRAKE. HENRY A. WALKER, St. Louis, Mo., assignor to the American Brake Company, St. Louis, Mo., a Corporation of Missouri. Filed Aug. 3, 1901. Serial No. 70,792. (No model.)

Claim.—1. In a locomotive brake-rigging, the combination with the main brake-lever pivoted at its upper end with the piston-rod of the brake-cylinder, and the push-rod connected to the lower end of said lever, of a movable filarum-block, to which the main lever is pivoted at an intermediate point, a guide for said filarum-block secured to the locomotive-frame, a ratchet-wheel and screw for adjusting the position of the filarum-block, and a take-up motor connected to the brake-cylinder for operating the ratchet-wheel.

2. In a locomotive brake-rigging, the combination of the main brake-lever pivoted at its upper end to the piston-rod of the brake-cylinder and at its lower end to the push-rod of the brake-rigging, a movable filarum-block pivoted to said lever at an intermediate point, a guide for said filarum-block secured to the locomotive-frame, and a take-up mechanism for automatically adjusting the position of the filarum-block when the brake-piston passes a certain point of its traverse.

696,528. BRAKE SLACK-ADJUSTER. HENRY A. WALKER, St. Louis, Mo., assignor to the American Brake Company, St. Louis, Mo., a Corporation of Missouri. Filed Aug. 3, 1901. Serial No. 70,786. (No model.)

Claim.—1. In a brake slack-adjuster, the combination with a tappet-rod and an arm movable with the brake piston-rod adapted to engage with the tappet, of a pawl-and-ratchet mechanism and a mechanical connection between the tappet-rod and pawl for actuating the same.

2. In a brake slack-adjuster, the combination with a tappet-rod having tappets, and an arm movable with the brake piston-rod adapted to engage said tappets, of a pawl-and-ratchet-driven screw and a bell-crank lever connected to the pawl and actuated by the tappet-rod.

3. In a brake slack-adjuster, the combination of a tappet-rod having tappets thereon, an arm secured to the brake piston-rod for engaging said tappets, a pawl-and-ratchet mechanism, a bell-crank lever for oper-

ating the pawl and another tappet on the rod for actuating the bell-crank lever.

4. In a brake slack-adjuster, the combination with a movable filarum-block and ratchet-driven screw, of a casing forming a guide for said filarum-block secured to the head of the brake-cylinder, a pawl and actuating means therefor supported from the casing, and a tappet-rod operated by the movement of the brake-piston.

5. In a brake slack-adjuster, the combination with a tappet-rod supported on the brake-cylinder and adapted to be operated by the movement of the brake-piston, of a pawl-and-ratchet mechanism and means for operating the pawl by the movement of the tappet-rod.

6. In a brake slack-adjuster, the combination with a tappet-rod operated by the movement of the brake-piston, of a pawl-and-ratchet mechanism, a lever for operating the pawl and a dog pivoted to one arm of the lever and adapted to engage with one of the tappets.

7. In a brake slack-adjuster, the combination of a movable filarum-block and ratchet-driven screw, a casing forming a guide for said filarum-block secured to the head of the brake-cylinder, a pawl and actuating means therefor supported from the casing, a tappet-rod operated by the movement of the brake-piston and a guide for said rod also supported from said casing.

696,527. HOLDBACK. RAYMOND W. WALKER, Oshkosh, Wis., assignor to the American Brake Company, St. Louis, Mo., a Corporation of Missouri. Filed Dec. 9, 1901. Serial No. 66,190. (No model.)

Claim.—A holdback comprising a suitable base-plate having outwardly-projecting lips or ears and a suitable hook, a locking-lever, a stationary pivot-pin connecting the locking-lever to and between the ears, grooved guides upon the plate and locking-lever respectively, a suitable spring having its projecting ends engaging the grooved guides whereby said ends are guided in their play in said grooves when the spring contracts and expands and retained against lateral motion, said spring engaging the pivot-pin, substantially as and for the purpose set forth.

696,528. SUPPORTING OR CONNECTING MEANS. EDWIN H. WALKER, Bridgeport, Conn., assignor to the Walker Brothers Company, Bridgeport, Conn., a Corporation. Filed Oct. 26, 1901. Serial No. 70,848. (No model.)

Claim.—1. In supporting or connecting means, the combination of a hook, a stud adjacent thereto and a socket adapted to disengage with said stud and close the mouth of the hook.

2. In supporting or connecting means, the combination of a hook

bearing a stud on its cheek, with a socket adapted to snap over said stud and close the mouth of the hook.

2. In supporting or connecting means, the combination of a hook bearing a stud on its cheek, with a flexibly-mounted socket adapted to snap over said stud and close the mouth of the hook.

3. In supporting or connecting means, the combination of a hook bearing a stud on its cheek, with means adapted to be connected with said hook and provided with a socket adapted to snap over said stud and close the mouth of the hook.

4. In supporting or connecting means, the combination of a hook bearing a stud on its cheek, with means adapted to be connected with said hook, said means having a hinged flap provided with a socket adapted to snap over said stud and close the mouth of the hook.

696,529. ELECTRIC HOSE-SIGNALING APPARATUS. Geo. S. Wertz, Hartford, Conn., assignor to the National Electric Hose Signaling Company, Boston, Mass., a Corporation of Delaware. Filed Dec. 5, 1899. Serial No. 26,770. (No model.)

Claim.—1. In a device of the character described, the combination of a half-coupling and a conducting-wire electrically connected thereto and leading therefrom along a length of attached hose, said wire having a portion of its length between its attached end and the length of hose looped sufficiently to provide for the separation of the hose and coupling without breaking the connection between the latter and said wire, for the purpose set forth.

2. In a device of the character described, the combination of a half-coupling provided with a contact-terminal, and a conducting-wire secured to said terminal and leading therefrom along a length of hose attached to said half-coupling, said wire having a circumferential coil located between its terminal and the length of hose, for the purpose set forth.

3. In a device of the character described, the combination of a half-coupling provided with a contact-terminal, and conducting-wires electrically connected to said half-coupling and contact-terminal respectively and leading therefrom along an attached length of hose, each of said wires having a portion of its length between its attached end and the length of hose looped or coiled sufficiently to provide for the separation of the hose and coupling without breaking the connection between said wires and the parts to which they are respectively connected, for the purpose set forth.

4. In a device of the character described, the combination of a half-coupling provided with a contact-terminal and with a circumferential groove, a conducting-wire secured to said terminal and having a coil lying in said groove, a length of hose secured to said half-coupling, and a packing-ring located between said coil of wire and the end of said hose.

5. In a device of the character described, the combination of a half-coupling provided with an annular abutment, a conducting-wire carried through said abutment and insulated therefrom and terminating in a metallic strip, and a yielding ring of insulating material interposed between said abutment and the free end of said strip and forming a support for the latter.

6. In a device of the character described, the combination of a half-coupling provided with an annular abutment, a conducting-wire carried through said abutment and insulated therefrom and terminating in a metallic strip, and a yielding ring of insulating material interposed between said abutment and the free end of said strip and forming a support for the latter, and means for preventing circumferential movement of said ring.

7. In a device of the character described, the combination of a half-coupling one of which is provided with an abutment, a conducting-wire carried through said abutment and insulated therefrom and terminating in a flexible, metallic strip, a yielding cushion of insulating material interposed between said abutment and said strip and forming a support for the latter, and a contact-terminal carried by the other half-coupling and insulated therefrom, and adapted to make contact with said strip.

8. In a device of the character described, the combination of a half-coupling one of which has an annular abutment provided with an annular groove, a rubber ring supported on said abutment over said groove and provided with an annular rib adapted to be expanded by the end of the opposing half-coupling, and cooperating contact-terminals carried by said half-couplings respectively, substantially as set forth.

9. In a device of the character described, a contact-terminal comprising a substantially rigid ring of insulating material, a metal ring embedded therein and flanged at its outer edge to provide a contact-surface, and a conducting-wire leading therefrom through said insulating-ring, for the purpose set forth.

10. In a device of the character described, a half-coupling provided with an internal, annular abutment, an insulating-ring supported thereon, a metal ring embedded in said insulating-ring and having a flange at its outer end, and a conducting-wire passed through the insulating-ring and its supporting-abutment and secured at its end to said flange, substantially as described.

11. In a device of the character described, in combination, two cooperating half-couplings one of which is provided with an insulating-ring having an annular conducting-ring secured to its edge and connected to a conducting-wire, the other half-coupling being provided with an annular abutment, an insulating-hub secured thereon, a conducting-wire passing through said hub and terminating in a metallic strip, and a yielding ring of insulating material located between said strip and abutment and forming a support for said strip, substantially as described.

696,530. BRAKE MECHANISM FOR VEHICLES. William Winkler, Syracuse, N. Y., assignor, by direct and mesne assignments, to George D. Galpin and Frank H. Brown, Syracuse, N. Y., and Elmer D. Goodrich, New York, N. Y. Filed Nov. 22, 1891. Serial No. 64,200. (No model.)

Claim.—1. A brake-operating mechanism comprising a series of three rotatable elements successively increasing in diameter, the one serving as a prime winding and unwinding medium, another as an intermediate tension-controller and the third largest one as the medium for directly and forcibly applying the braking power, a pull device engaging the said elements, and means in connection with all the elements for synchronously operating the same in proper-timed relation.

2. A brake-operating mechanism comprising an initially-rotating drum, a larger intermediate drum, and a power-applying drum greater in diameter than the other drums, the said drums being disposed in alignment, means for causing a synchronous operation of the drums in timed relation and proper direction of rotation, and a pull device engaging the said drums.

3. A brake mechanism comprising a brake-beam with cheeks, means for directly moving the said brake-beam, a series of successively-arranged rotatable elements gradually increasing in diameter and having means for synchronously and properly rotating the same, and a pull device connected to the means for directly moving the brake-beam and engaging the said elements, said pull device being held normally taut.

4. A brake-operating mechanism comprising a series of rotatable elements successively increasing in diameter, means for operatively connecting the said elements whereby the rotation of one will synchronously rotate the others and impart to the latter a proper direction of movement, and a pull device engaging all of the said elements.

5. A brake-operating mechanism comprising a series of rotatable elements successively increasing in diameter, means for operatively connecting the said elements whereby the rotation of one will synchronously rotate the others and impart to the latter a proper direction of movement, and a pull device engaging all of the said elements.

rotating the said elements whereby the rotation of one will synchronously rotate the others and impart to the latter a proper direction of movement, and a pull device engaging all of said elements and adapted to be wound on and unwound from the initially-rotated element and to be normally coiled around the remaining elements.

6. A brake-operating mechanism comprising a series of rotatable elements successively increasing in diameter, means for operatively connecting the said elements whereby the rotation of one will synchronously rotate the others and impart to the latter a proper direction of movement, the said elements having a reverse direction of rotation in alternation, and a pull device engaging all of the said elements.

7. A brake-operating mechanism comprising a series of rotatable elements successively increasing in diameter, means for operatively connecting the said elements whereby the rotation of one will synchronously rotate the others and impart to the latter a proper direction of movement, the said elements having a reverse direction of rotation in alternation, and a pull device engaging all of said elements and adapted to be wound on and unwound from the initially-rotated element and to be normally coiled around the remaining elements and to move on and off from diametrically opposite portions of said remaining elements.

696,531. PNEUMATIC CONVEYER. James H. Adams, Cayce, N. C. Filed June 1, 1891. Serial No. 26,749. (No model.)

Claim.—1. In a device of the character described, a fan, a discharge-chute leading from said fan, a feed-hopper, a chute leading from said hopper into the eye or inlet of said fan, a chute leading from said hopper into the discharge from said fan, and means whereby the material fed into said hopper may be conducted into either of said chutes, substantially as described.

2. In a device of the character described, a fan, a discharge-chute leading from said fan, a feed-hopper, a chute leading from said hopper into the eye or inlet of said fan, a chute leading from said hopper into the discharge from said fan, and a valve within said hopper and adapted to alternately close the inlets to said chutes, whereby the material may be conducted into either of said chutes, substantially as described.

3. In a pneumatic grain-conveyer, a fan-casing, a reversible fan therein, a chute leading to the interior of said casing through the air-intake thereof, a chute leading from said fan-casing to the blast-discharge of said casing, and means to cut off the passage of material through either of said chutes, substantially as described.

4. In a pneumatic grain-conveyer, a closed chute, means for inducing artificial air-currents through said chute, laterally, and downwardly-diverging opening branches at the outer end of said chute whereby the grain is uniformly distributed laterally and downwardly from the discharge end of said chute, substantially as described.

5. In a pneumatic grain-conveyer, a fan-casing, a reversible fan therein, a chute leading to the interior of said casing, and a chute leading from said fan-casing to the blast-discharge of said casing, one of said chutes having check-valves for the purpose set forth, substantially as described.

6. In a pneumatic grain-conveyer, a fan-casing having a discharge-chute and an air-intake, a reversible fan in said casing, a chute 8 leading to said casing, a chute 10 leading from chute 8 to said discharge-chute, and means to cut off the passage of material through either of said chutes 8, 10, substantially as described.

7. In a pneumatic grain-conveyer, an inclined chute through which induced air-currents are caused to pass, an extension-chute slidably disposed with relation to said first-mentioned chute, and with lateral branches at its discharge end and downwardly-opening branches near said lateral branches, substantially as described.

8. In a pneumatic grain-conveyer, an inclined conveyor-chute through which induced air-currents are caused to pass, laterally-curved branches at the outlet end of said conveyor-chute, a centrally-disposed downwardly-projecting chute at the discharge end of said conveyor-chute and downwardly and laterally and reversely projecting chutes at the discharge end of said conveyor-chute, whereby means are provided for the lateral discharge of the air-currents, and the lateral and downward discharge of the material carried through the said conveyor-chute, substantially as described.

696,532. TOOL FOR CUTTING CAST TYPE-LINES IN LINO-TYPE-MACHINES. Charles A. Albrecht, Berlin, Germany. Filed Oct. 12, 1891. Serial No. 71,690. (No model.)

Claim.—1. In a mechanism for trimming the cast type-lines in linotype-machines, the combination with a slide *g*, of a knife *f* rigidly fixed in the slide, a knife *e* threaded on the end *d* opposite to the cutting edge, a nut *c* in form of a disk situated upon the spindle of the knife *e* and provided with grooves *b* on its circumference, a lever *a* pressed against the circumference of the disk *c* and a spring *h* fixed to the slide *g* and directed so as to press the knife *e* toward the knife *f* substantially as described and for the purpose set forth.

2. In a mechanism for trimming the cast type-lines in linotype-machines, the combination with a slide *g*, of a knife *f* rigidly fixed in the slide, a knife *e* threaded on the end *d* opposite to the cutting edge, a nut *c* in form of a disk situated upon a spindle of the knife *e* and provided with grooves *b* on its circumference, a lever *a* pressed against the circumference of the disk *c* and a spring *h* fixed to the slide *g* and directed so as to press the knife *e* toward the knife *f*, a pin *i* fixed to the slide *g* and a pin *k* fixed to the disk *c*, both pins being situated in the same distance from the center line of the spindle *d* substantially as described and for the purpose set forth.

696,533. WINDER-STAY FASTENER AND HOLDER. Arthur L. Ammann, Seattle, Wash., Cal. Filed Sept. 28, 1891. Serial No. 71,691. (No model.)

Claim.—1. In a winder-stay fastener, and in combination with a winder-stay having a slit formed therein, a plate formed with an integral tongue adapted to be passed through said slit and clamped to hold said stay in place, and bent at its upper end to form an integral hook adapted for the passage of the stay, substantially as described.

2. In a winder-stay fastener, the combination with a bridle-blind comprising leather piles and a reinforcing-plate inserted between said piles, of a winder-stay having its connected and passed downwardly between one of the piles and said reinforcing-plate and fitted, and a fastener consisting of a metallic plate bearing against one of the piles and provided with an integral tongue projecting through said ply, the connecting-plate and the slit in the stay and clamped to hold said stay in position and further provided at its upper end with an integral hook having a guide-slot through which the stay projects, said hook being bent over the upper edges of the piles and reinforcing-plate and down against the surface of the ply opposite that against which it bears for clamping the parts together, substantially as and for the purpose set forth.

696,534. CURTAIN-POLE. James Adams, Waterville, Conn., assignor to Durbacher & Burdick Manufacturing Company, Waterville, Conn., a Corporation of Connecticut. Filed Jan. 6, 1893. Serial No. 26,697. (No model.)

Claim.—1. A ball or knob for attachment to curtain-poles or rods, said knob consisting of two sections having their adjacent edges locked together, and a disk having its edge locked between the adjacent edges of said sections and provided with spring-fingers adapted to bear upon said rod and removably hold the knob thereon, substantially as described.

2. A hollow knob or ball consisting of two sections having their adjacent edges flanged and locked together, one of said sections being provided with an opening, and a disk formed of spring metal having its edge clamped between the flanged edges of said sections and provided with radial fingers bent and shaped as described, in combination with a curtain-pole, the end of which is adapted to pass through the opening in said section and between said radial fingers whereby the knob may be attached to and detached from said pole, substantially as described.

696,535. ADJUSTABLE TRUCK. HENRY R. BAILEY, New Fountain City, Ind. Filed Sept. 3, 1901. Serial No. 74,300. (No model.)

Claim.—1. In an adjustable truck, the combination of a deck with holes along the edges of its longer sides, headlights secured at either end of the deck, castings secured near each of the corners of the deck, perpendicular slots near the outer edges of the castings, arms adapted to move up and down in said slots, means for holding the arms in said slots at any point by means of pins to be inserted in holes extending through the arms and through the upper part of the castings, axes provided on the lower ends of each of the arms and at right angles thereto, and wheels provided with epicycloids on their peripheries, adapted to revolve on said axes, all substantially as shown and described and for the purposes set forth.

2. In an adjustable truck, a deck provided with standards loosely inserted in holes in the edges thereof, in combination with castings secured to the corners of the deck, perpendicular slots provided in the outer edges of the castings, arms adapted to slide up and down in said slots and adapted to be secured at any point desired, axes which extend out at right angles from the lower ends of said arms, wheels mounted on said axes, a multiple of epicycloids extending outward from the periphery of each wheel, all substantially as shown and described and for the purposes specified.

696,536. APPARATUS FOR AUTOMATICALLY COATING MECHANICAL PARTS. THOMAS E. BAKER, London, and WILLIAM T. BAKER, Charlton, England. Filed Nov. 13, 1900. Serial No. 34,344. (No model.)

Claim.—1. In a coating-machine, the combination with a stencil-plate and a feed-column to contain the articles intended for treatment, of a reciprocating plate which receives the articles from the feed-column, a lifter to raise the articles from the reciprocating plate to the stencil-plate and an operative connection between the lifter and the reciprocating plate whereby the latter places the articles over the lifter and after they have been treated ejects the same from the lifter, substantially as set forth.

2. In a coating-machine, the combination with a stencil-plate, of a hollow lifter serving also as a discharger, tubular extensions each communicating with the interior of the lifter, an elastic tube within each extension, a shoulder in the lifter to support the bottom of each elastic tube, means to raise the lifter toward the stencil-plate, and means to produce a partial vacuum within the lifter, substantially as and for the purposes set forth.

3. In a coating-machine, the combination with a stencil-plate, of a hollow lifter serving also as a discharger, tubular extensions each communicating with the interior of the lifter, an elastic tube within each extension, a shoulder in the lifter to support the bottom of each elastic tube, means to raise the lifter toward the stencil-plate, and means to produce a vacuum within the lifter when thus raised, substantially as set forth.

4. In a coating-machine, the combination with a stencil-plate, of a hollow lifter serving also as a discharger, tubular extensions each communicating with the interior of the lifter by a relatively restricted passage, an elastic tube within each extension, a shoulder in the lifter to support the bottom of each elastic tube, means to raise the lifter toward the stencil-plate and means to produce a vacuum within the lifter when thus raised, substantially as set forth.

5. In a coating-machine, the combination with a stencil-plate and a hopper movable relatively thereto, of a lever operatively connected with the lifter, a driving-shaft, a cam on that shaft to cooperate with that lever, a pedal, an elastic connection between that pedal and the above-mentioned lever comprising a spring, a feed-column to contain the articles intended for treatment, a feeder-plate, a hollow lifter serving also as a discharger, tubular extensions each communicating with the interior of the lifter by a relatively restricted passage, an elastic tube within each extension, a shoulder in the lifter to support the bottom of each elastic tube, a vacuum vessel, a conduit connecting the interior of the vacuum vessel with that of the lifter, a vacuum-regulator in that conduit and an operative connection between the feeder-plate the lifter and the regulator, substantially as set forth.

6. In a coating-machine, the combination with a stencil-plate and a hopper movable relatively thereto, of a lever operatively connected with the lifter, a driving-shaft, a cam on that shaft to cooperate with that lever, a pedal and an elastic connection between that pedal and the above-mentioned lever comprising a spring, substantially as set forth.

7. In a coating-machine, the combination with a stencil-plate and a hopper movable relatively thereto, of an operative connection between them, a feed-column to contain the articles intended for treatment, a feeder-plate, a lifter to elevate the articles from the feeder-plate to the stencil-plate, an operative connection between the feeder-plate and the lifter, a conveyor, a table upon the conveyor, a second feeder-plate and a second feed-column upon that table, and an operative connection between the conveyor, the second feeder-plate and the hopper and stencil-plate above, substantially as set forth.

696,537. TENSIONING-MACHINE. JAMES A. BARNES, Oshkosh, Wis. Filed Dec. 28, 1901. Serial No. 64,573. (No model.)

Claim.—1. In a tensioning-machine the combination with a standard having vertical slides or ways on one side a vertically-movable carriage for the tensioning outer-rod mounted on said slides or ways and extending around the standard having vertical slides or ways opposite those on the standard, a second vertically-movable carriage mounted on the slides of the said first carriage and having horizontal slides or ways thereon, a caper-rod support fixed to the said horizontal slides and means for moving

the respective carriage and roller-support in their paths for the purpose set forth.

2. The combination in a tensioning-machine of a standard having vertical ways or slides on one side, of a carriage mounted thereon having a tensioning outer-rod journaled thereon and having its slides extending around the standard, vertical slides or ways on the rear extending sides of said carriage, another carriage mounted on said slides or ways and having horizontal slides thereon, a frame having vertical and horizontal journals fitted to the horizontal slides, a horizontal shaft journaled in the said frame having a pulley mounted thereon and a bevel-gear secured to one end thereof, a vertical shaft mounted in the vertical journals having a bevel-gear secured thereto adapted to mesh with the other said bevel-gear and means for rotating the horizontal shaft for the purpose set forth.

3. In a tensioning-machine the combination with standards, vertically-movable carriages mounted thereon and means for sliding said carriages in their paths, vertically-movable frames mounted on the said carriages having horizontal slides thereon, brackets or journal-supports mounted in said horizontal slides, journaled horizontally in the said brackets and having pulleys mounted thereon each shaft having a bevel-gear secured to one of the ends thereof, caper-rod journaled vertically in the brackets and having a bevel-gear secured to each roller adapted to mesh with the other or horizontally-mounted bevel-gears and means for rotating the horizontal shaft for the purpose set forth.

4. In a tensioning-machine the combination with a standard, a vertically-movable carriage mounted thereon, having a screw for moving same, a second carriage mounted on the first carriage and adjustable vertically thereon, by means of a screw, a horizontally-movable frame mounted on the second carriage and a screw for adjusting the same, horizontal and vertical shafts journaled in said frame at right angles to each other, bevel-gears adapted to connect the two said shafts, a caper-rod head secured to one end of the vertical shaft and means for rotating the horizontal shaft for the purpose set forth.

5. In a tensioning-machine the combination with the bed or main support having a driving-shaft journaled therein, a driving-pulley mounted on said shaft, the base 3 mounted on said bed, a vertical standard secured to said base, a vertically-movable carriage mounted on the standard, a horizontal tensioning outer-rod journaled thereon, a pulley on said outer-rod, a horizontal shaft mounted adjustably in the said carriage, a vertical caper-rod mounted adjustably on said carriage but movable with the said horizontal shaft, bevel-gears for connecting the said horizontal shaft and vertical outer-rod, another standard secured to the base, a vertical adjustable pulley-frame mounted on said independent standard and means for adjusting same, a horizontal caper-rod mounted thereon and adjustable vertically, and having a pulley secured thereto and means for adjusting the same, a single belt passing over and around the several mentioned pulleys and around the pulley on said driving-shaft and means for tightening said belt and rotating the driving-shaft substantially as shown and described.

6. In a tensioning-machine a standard 4 a vertically-movable carriage 5 for the main tensioning outer-rod, a second carriage 15 vertically movable thereon, a frame 37 mounted on the second carriage and movable horizontally, a horizontal shaft and vertical outer-rod 30 bevel-gears 39 to connect the said shafts a pulley-frame 38 secured standard 40 for same mounted on the base 3 a caper-rod mounted on the said standard 40 and adjustable vertically thereon.

7. In a tensioning-machine the combination with a base, a vertical standard mounted thereon, a carriage mounted on said standard and adjustable vertically, another carriage mounted on the above-said carriage and capable of being adjusted vertically, a frame 37 mounted on the latter carriage and capable of horizontal movement, a shaft journaled in said frame and having a pulley secured to the middle thereof and a bevel-gear secured to the end thereof, a vertical caper-rod journaled in the said frame and having a bevel-gear secured thereto, said gear adapted to mesh with the other said gear, a caper-rod head secured to one end of said outer-rod, and a balance-wheel secured to the other end and means for rotating said pulley for the purpose specified.

8. In a machine of the class described the combination with a base 3, of a standard 4, a carriage mounted thereon and capable of vertical movement thereon and having tensioning outer-rod journaled thereon, vertical caper-rod mounted on said carriage and capable of independent horizontal and vertical adjustment thereon, another standard secured to the base in advance of the said standard 4, and having the extending portion 41, a pulley-frame attached to the said extension and capable of vertical adjustment thereon, slides or ways on the front side of the standard 40, a carriage mounted on said slides, and capable of vertical adjustment thereon, a bracket 46 mounted on the last-said carriage and capable of horizontal adjustment, a caper-rod journaled in the said bracket and having a saw attached to the end thereof, and means for universally adjusting the several outer-rod rollers and saw for the purpose specified.

9. In a tensioning-machine the combination with a base 3, of a standard 4 having a vertically-movable carriage mounted thereon, the tensioning-rod 15 carrying the outer-rod, 15' journaled in said carriage and adjustable vertically thereon, caper-rod 30 journaled in the said carriage 15 and having the outer-heads 17 secured thereto, the pulley-frame support 40, the pulley-frame 38, means for moving the standard 4 axially with the main outer-rod rollers 13, and means for moving the said standard to the base in one position, whereby when the said standard is moved away from the pulley-frame 38 the tensioning outer-rod rollers may be removed for the purpose specified.

696,538. CATANEMIAL BANDAGE. HENRY R. BAILEY, New York, N. Y. Filed Aug. 1, 1901. Serial No. 74,467. (No model.)

Claim.—1. A catanemial bandage composed of a flexible body, a flat strip of sponge permanently secured to said body along its sides, but disconnected therefrom at its ends, to form a flat, flexible, open-ended tube, substantially as specified.

2. A catanemial bandage composed of a strip of sponge, a flexible body that overlaps the sides of the sponge and projects beyond its ends, and a gathering-string drawn through the exposed ends of the body, the sponge being connected to the body along its sides but disconnected therefrom along its ends, substantially as specified.

696,539. MAGAZINE-PISTOL. THOMAS J. BARNETT, Orange, N. J., assignor to himself, and Henry Berg, Orange Valley, N. J. Filed Dec. 11, 1901. Serial No. 64,699. (No model.)

Claim.—1. In a revolver or similar firearm, the combination, with the revolver-frame and a revolving cylinder in said frame, of a hammer hung upon a pivot in said frame, a locking-lever connected with said frame and arranged directly above the said revolving cylinder, and means on said hammer adapted to engage with said locking-lever to hold said

lever in its fixed position during the firing of a cartridge, substantially as and for the purposes set forth.

2. In a revolver or similar firearm, the combination, with the revolver-frame and a revolving cylinder in said frame, of a hammer hung upon a pivot in said frame, a locking-lever connected with said frame and arranged directly above the said revolving cylinder, and a forwardly-projecting holding-dog on said hammer adapted to engage with said locking-lever to hold said lever in its fixed position during the firing of a cartridge, substantially as and for the purposes set forth.

3. In a revolver or similar firearm, the combination, with the revolver-frame, and a revolving cylinder in said frame, of a hammer hung on a pivot in said frame, a locking-lever pivotally connected with said frame and arranged directly above the said revolving cylinder, and means on said hammer adapted to engage with the rear end of said pivoted locking-lever to hold said lever in its fixed position during the firing of a cartridge, substantially as and for the purposes set forth.

4. In a revolver or similar firearm, the combination, with the revolver-frame, of a revolving cylinder in said frame, of a hammer hung on a pivot in said frame, a locking-lever pivotally connected with said frame and arranged directly above the said revolving cylinder, and a forwardly-projecting holding-dog on said hammer adapted to engage with the rear end of said pivoted locking-lever to hold said lever in its fixed position during the firing of a cartridge, substantially as and for the purposes set forth.

5. In a revolver or similar firearm, the combination, with the revolver-frame, of a revolving cylinder in said frame, and lifting protuberances or projections upon the outer cylindrical surface of said cylinder, and a locking-lever pivotally connected with said frame and arranged directly above the said revolving cylinder with which the said protuberances or projections on said cylinder are brought in engagement for lifting the said locking-lever, substantially as and for the purposes set forth.

6. In a revolver or similar firearm, the combination, with the revolver-frame, of a revolving cylinder in said frame, and lifting protuberances or projections upon the outer cylindrical surface of said cylinder, a locking-lever pivotally connected with said frame and arranged directly above the said revolving cylinder with which the said protuberances or projections on said cylinder are brought in engagement for lifting the said locking-lever, a hammer hung on a pivot in said frame, and means on said hammer adapted to engage with the rear end of said pivoted locking-lever to hold said lever in its fixed position during the firing of a cartridge, substantially as and for the purposes set forth.

7. In a revolver or similar firearm, the combination, with the revolver-frame, of a revolving cylinder in said frame, and lifting protuberances or projections upon the outer cylindrical surface of said cylinder, a locking-lever pivotally connected with said frame and arranged directly above the said revolving cylinder with which the said protuberances or projections on said cylinder are brought in engagement for lifting the said locking-lever, a hammer hung on a pivot in said frame, and a forwardly-projecting holding-dog on said hammer adapted to engage with the rear end of said pivoted locking-lever to hold said lever in its fixed position during the firing of the cartridge, substantially as and for the purposes set forth.

8. In a revolver or similar firearm, the combination, with the revolver-frame, of a revolving cylinder in said frame, the said cylinder being made with a series of cartridge-receiving channels 19 and chambers 21 in alignment with said channels, and a locking-lever arranged directly above the said cylinder, said lever being provided in its under surface with a channel adapted to be fitted directly above the uppermost channel 19 in said cylinder to form a complete chamber, a hammer hung upon a pivot in said frame, and means on said hammer adapted to engage with said locking-lever while firing a cartridge, substantially as and for the purposes set forth.

9. In a revolver or similar firearm, the combination, with the revolver-frame, of a revolving cylinder in said frame, the said cylinder being made with a series of cartridge-receiving channels 19 and chambers 21 in alignment with said channels, and a locking-lever arranged directly above the said cylinder, said lever being provided in its under surface with a channel adapted to be fitted directly above the uppermost channel 19 in said cylinder to form a complete chamber, a hammer hung upon a pivot in said frame, and a forwardly-projecting holding-dog on said hammer adapted to engage with said locking-lever while firing a cartridge, substantially as and for the purposes set forth.

10. In a revolver or similar firearm, the combination, with the revolver-frame, of a revolving cylinder in said frame, the said cylinder being made with a series of cartridge-receiving channels 19 and intermediate-placed ribs 20, and also with chambers 21 in alignment with said channels 19, lifting protuberances or projections upon said cylinder in alignment with said ribs 20, a locking-lever pivotally connected with said frame and arranged directly above the said revolving cylinder with which the protuberances or projections on said cylinder are brought in engagement for lifting the said locking-lever, substantially as and for the purposes set forth.

engagement for lifting the said locking-lever, substantially as and for the purposes set forth.

11. In a revolver or similar firearm, the combination, with the revolver-frame, of a revolving cylinder in said frame, the said cylinder being provided with a series of cartridge-receiving channels 19 and intermediate-placed ribs 20, and also with chambers 21 in alignment with said channels 19, lifting protuberances or projections upon said cylinder in alignment with said ribs 20, a locking-lever pivotally connected with said frame and arranged directly above the said revolving cylinder with which the protuberances or projections on said cylinder are brought in engagement for lifting the said locking-lever, a hammer hung on a pivot in said frame, and means on said hammer adapted to engage with the rear end of said pivoted locking-lever to hold said lever in its fixed position while firing a cartridge, substantially as and for the purposes set forth.

12. In a revolver or similar firearm, the combination, with the revolver-frame, of a revolving cylinder in said frame, the said cylinder being provided with a series of cartridge-receiving channels 19 and intermediate-placed ribs 20, and also with chambers 21 in alignment with said channels 19, lifting protuberances or projections upon said cylinder in alignment with said ribs 20, a locking-lever pivotally connected with said frame and arranged directly above the said revolving cylinder with which the protuberances or projections on said cylinder are brought in engagement for lifting the said locking-lever, a hammer hung on a pivot in said frame, and a forwardly-projecting holding-dog on said hammer adapted to engage with the rear end of said pivoted locking-lever to hold said lever in its fixed position while firing a cartridge, substantially as and for the purposes set forth.

13. In a revolver or similar firearm, the combination, with the revolver-frame and a revolving cylinder, having open cartridge-receiving channels and chambers in alignment with said channels, of a cartridge-magazine, and means connected with said magazine and said frame for pivotally securing the said magazine at the one side of said frame, substantially as and for the purposes set forth.

14. In a revolver or similar firearm, the combination, with the revolver-frame and a revolving cylinder, having open cartridge-receiving channels and chambers in alignment with said channels, of a cartridge-magazine, means connected with said magazine and said frame for pivotally securing said magazine at the one side of said frame, and a spring secured to said frame having a curved upper end portion with which the lower end portion of said magazine is in sliding and holding engagement, substantially as and for the purposes set forth.

15. In a revolver or similar firearm, the combination, with the revolver-frame and a revolving cylinder, having open cartridge-receiving channels and chambers in alignment with said channels, of a cartridge-magazine, means connected with said magazine for pivotally arranging said magazine at the side of the revolver-frame, consisting of a shield and a bracket, both provided with pivotal ears with which a portion of said magazine is pivotally connected, substantially as and for the purposes set forth.

16. In a revolver or similar firearm, the combination, with the revolver-frame and a revolving cylinder, having open cartridge-receiving channels and chambers in alignment with said channels, of a cartridge-magazine, means connected with said magazine for pivotally arranging said magazine at the side of the revolver-frame, consisting of a shield and a bracket, both provided with pivotal ears with which a portion of said magazine is pivotally connected, and a spring secured to said frame having a curved upper end portion with which the lower end portion of said magazine is in sliding and holding engagement, substantially as and for the purposes set forth.

17. In a revolver or similar firearm, the combination, with the revolver-frame and a revolving cylinder, having open cartridge-receiving channels and chambers in alignment with said channels, of a cartridge-magazine, means connected with said magazine for pivotally arranging said magazine at the side of the revolver-frame, consisting of a shield and a bracket, both provided with pivotal ears, and a pair of links pivotally attached at their lower ends to the ears of said shield and said bracket, and also pivotally attached at their upper ends to the body of said magazine, substantially as and for the purposes set forth.

18. In a revolver or similar firearm, the combination, with the revolver-frame and a revolving cylinder, having open cartridge-receiving channels and chambers in alignment with said channels, of a cartridge-magazine, means connected with said magazine for pivotally arranging said magazine at the side of the revolver-frame, consisting of a shield and a bracket, both provided with pivotal ears, a pair of links pivotally attached at their lower ends to the ears of said shield and said bracket, and also pivotally attached at their upper ends to the body of said magazine, and a spring secured to said frame having a curved upper end portion with which the lower end portion of said magazine is in sliding and holding engagement, substantially as and for the purposes set forth.

19. In a revolver or similar firearm, the combination, with the re-

volver-frame, and a revolving cylinder, of a locking-lever 25 pivotally connected with the said frame and arranged directly above the said cylinder, and means at the free end of said lever adapted to engage with a portion of the revolver-frame to limit the upward movement of said lever, substantially as and for the purposes set forth.

20. In a revolver or similar firearm, the combination, with the revolver-frame, and a revolving cylinder, of a locking-lever 25 pivotally connected with the said frame and arranged directly above the said cylinder, and means at the free end of said lever adapted to engage with a portion of the revolver-frame to limit the upward movement of said lever, consisting, essentially, of a recessed member on said frame, and a projection on the rear end of said lever extending into said recessed member and capable of a limit movement in the recess of said member, substantially as and for the purposes set forth.

21. In a revolver or similar firearm, the combination, with the revolver-frame and a revolving cylinder, of a fire-shield on one side of said frame arranged to cover a portion of said cylinder, said shield being formed with an opening, and a cartridge-magazine or shell-holder pivotally secured to the said shield and having a portion extending into and through the opening in said shield, substantially as and for the purposes set forth.

22. In a revolver or similar firearm, the combination, with the revolver-frame and a revolving cylinder, of a fire-shield on one side of said frame arranged to cover a portion of said cylinder, said shield being formed with an opening, a cartridge-magazine or shell-holder pivotally secured to said shield, and having a portion extending into and through said opening in the shield, and a spring secured to the side of the revolver-frame having its upper end normally in holding engagement with a portion of said cartridge-magazine or shell-holder, substantially as and for the purposes set forth.

23. In a revolver or similar firearm, the combination, with the revolver-frame and a revolving cylinder, of a fire-shield on one side of said frame arranged to cover a portion of said cylinder, a cartridge-magazine or shell-holder, a means of pivotal connection on said shield, a means of pivotal connection on the body of said magazine or shell-holder, and a connecting means between said means of pivotal connection on said shield and said means of pivotal connection on said magazine or shell-holder, substantially as and for the purposes set forth.

696,540. EMBROIDERY-SEAM. CHARLES E. BENTLEY, New York. Filed Aug. 7, 1901. Serial No. 71,195. (No model.)

Claim.—1. An embroidery-seam comprising fabric, two crossing upper threads and two aligned crossing under threads fastened to the fabric at opposite edges of the seam, and spangles or analogous ornaments sustained between the upper and under threads and intermediately of the width of the seam, the thread portions lying at one face of each spangle being looped through the openings of the spangles and interlocked therewith by passage through said loops of the other thread portions lying at the opposite face of the spangles or ornaments, substantially as described.

2. An embroidery-seam comprising fabric, two crossing needle-threads and two aligned crossing shuttle-threads ranging in zigzag course along the seam, and spangles or analogous ornaments sustained between the upper and under threads and intermediately of the width of the seam, the thread portions lying at one face of each spangle being looped through the openings of the spangles and interlocked therewith by the shuttle-threads, said needle-threads being then looped through the shuttle-threads, said needle-threads then being looped through the fabric at the other edge of the seam and thence interlocked by the shuttle-threads; said threads thence passing diagonally again to the spangle-openings and interlocking therewith and passing thence to and interlocking at the fabric, and so on along the seam, substantially as described.

3. An ornamental open-work embroidery-seam comprising two opposed and substantially parallel pieces of fabric, two crossing needle-

threads and two aligned crossing shuttle-threads ranging in zigzag course along the seam, and spangles or analogous ornaments sustained between the upper and under threads and intermediately of the width of the seam, and between two crossing portions of needle-threads and two crossing portions of shuttle-threads; the needle-threads being first looped through one piece of fabric near its edge and thence interlocked by the shuttle-threads, said needle-threads being then looped through the spangle-openings and thence interlocked by the shuttle-threads, said needle-threads then being looped through the other piece of fabric near its edge and thence interlocked by the shuttle-threads; said threads thence passing diagonally again to the spangle-openings and interlocking therewith and passing thence to and interlocking at the first piece of fabric, and so on along the seam, substantially as described.

696,541. EMBROIDERY-SEAM. CHARLES E. BENTLEY, New York. Filed Aug. 7, 1901. Serial No. 71,196. (No model.)

Claim.—1. An embroidery-seam comprising fabric, two rows of stitches in the fabric one row at each edge of the seam, and a braid or ribbon folded back and forth diagonally between the edges of the seam and secured to the fabric by the rows of fastening-stitches within the folds of the braid or ribbon, substantially as described.

2. An embroidery-seam comprising fabric, a braid or ribbon ranging in zigzag course along the seam and diagonally folded upon itself at opposite edges of the seam, and two rows of fastening-stitches holding the braid or ribbon to the fabric, the threads of said fastening-stitches passing in a loop around the braid or ribbon under each of its folds and above the fabric and then passing in series of stitches through the braid and fabric and interlocking with the shuttle-threads along opposite edges of the seam, said upper threads being connected at the folds of the braid or ribbon, substantially as described.

3. An embroidery-seam comprising fabric, a braid or ribbon ranging in zigzag course along the seam and diagonally folded upon itself at opposite edges of the seam, and two rows of fastening-stitches holding the braid or ribbon to the fabric, each row of stitches comprising a needle-thread and a shuttle-thread interlocking therewith, said needle-threads passing in loops around the braid or ribbon at its folds and above the fabric and then passing in series of stitches through the braid and fabric and interlocking with the shuttle-threads along opposite edges of the seam, said upper threads being connected at the folds of the braid or ribbon, substantially as described.

696,542. BROOK-BOLDER. RICHARD BLOOM, Oakland, Cal. Filed May 15, 1901. Serial No. 69,349. (No model.)

Claim.—The combination with a base-plate, of a spring-actuated hinge-plate provided with laterally-projecting studs and reversibly-projecting fingers, arms pivoted to the base-plate and provided with distal extensions into which the studs of the hinge-plate project and by means of which when the hinge-plate is depressed said arms will be swung downwardly, substantially as set forth.

696,543. CORN-PLANTER. WILLIAM L. BOWEN, Columbus, Miss. Filed Nov. 7, 1901. Serial No. 51,402. (No model.)

Claim.—1. In a seedling-machine, the combination with a seed-receptacle having an opening in its bottom and a supporting-plate beneath said bottom and having a discharge-hole therein, of an oscillatory seed-plate disposed between the bottom of the receptacle and the supporting-plate and having an opening therein, a spring secured above the seed-plate, a cut-off secured to the free end of said spring and means for oscillating the seed-plate back and forth under said cut-off to control the discharge of seed through the supporting-plate.

2. In a seedling-machine, the combination with a seed-receptacle having an opening in its bottom and a supporting-plate beneath said bottom and having holes therein through which the seed is dropped, of a seed-plate disposed between the supporting-plate and seed-receptacle and having openings therein to receive the seed, a spring, cut-off secured to the ends of said spring and engaging the seed-plate to prevent the escape of any but the contents of the openings in the seed-plate, and means for oscillating the seed-plate back and forth under said cut-off.

3. In a seedling-machine, the combination with a supporting-plate having discharge-dents at respective sides of its center, a receptacle mounted upon said supporting-plate and provided in its bottom with openings at respective sides of its center for the escape of seed, of a seed-plate located between said receptacle and supporting-plate and having holes therein to receive grain from the openings in the bottom of the receptacle, a spring secured between its ends, cut-off secured to the respective ends of said spring and resting upon the seed-plate, and means for oscillating said seed-plate to move the holes therein back and forth under the respective cut-off.

4. In a seedling-machine, the combination with a divided seed-receptacle having openings in its bottom and a supporting-plate to which the receptacle is hinged and made with openings at opposite sides of its center, of a coupling having dents or passages therein communicating with said openings, a discharge hose or spout common to both dents or passages, a seed-plate between the supporting-plate and receptacle and adapted to convey the seed to said dents or passages, means for oscillating said plate and cut-off carried by the receptacle to limit the amount of seed carried by the seed-plate.

5. In a seedling-machine, the combination with a seed-receptacle and a partition therein dividing the receptacle into two compartments, of a seed-plate having a hole under each compartment of the receptacle and adapted to drop the grain from both, spring-pressed cut-off at respective sides of the partition and means for oscillating said seed-plate.

6. In a seedling-machine, the combination with a seed-receptacle having an opening in its bottom and divided by a central partition, of a circular seed-plate mounted to oscillate beneath the opening in the receptacle and adapted to convey the seed beneath the partition where it drops the seed, a spring secured beneath the partition, cut-off carried by the ends of the spring and bearing on the seed-plate, and means for oscillating the seed-plate.

7. In a seedling-machine, the combination with a seed-receptacle, of a seed-plate mounted to oscillate beneath the receptacle and drop the seed, a lever having arms at one end and to fit in grooves or recesses in the seed-plate, legs on the arms to enter openings in the plate, and means for oscillating the plate.

696,544. PACKING. FRANKLIN BROWN, Philadelphia, Pa., assignor to Clement Bantala, Philadelphia, Pa. Filed Sept. 26, 1901. Serial No. 73,254. (No model.)

Claim.—1. A packing comprising the packing proper consisting of yielding cushion, a covered absorbent cushion disposed back of one of said sections and having its parts arranged to slide one upon the other,

and a member back of the other section designed to retain the lubricant, the whole inclosed in a textile casing, substantially as described.

2. A packing comprising the packing proper consisting of yielding sections, a covered absorbent cushion disposed back of one of said sections and having its parts arranged to slide one upon the other, a yielding core interposed between the separate parts of said cushion, and an india-rubber cushion disposed back of the other section and acting to retain the lubricant, the whole inclosed in a textile casing, substantially as described.

696,545. DENTAL-ENGINE WALL-BRACKET. ARTHUR W. BROWNE, Princeton, N. Y., assignor to The S. & W. White Dental Manufacturing Company, Philadelphia, Pa. Filed July 1, 1901. Serial No. 64,645. (No model.)

Claim.—1. In a folding dental-engine wall-bracket, the combination of a main arm pivoted to swing vertically, a forearm pivoted to the outer end of said main arm, a gear on the inner end of said forearm and a pivoted rod provided with a rack meshing with the gear of said forearm, substantially as and for the purpose described.

2. In a folding dental-engine wall-bracket, the combination of a main arm pivoted to swing vertically, a forearm pivoted to the outer end of said main arm, and adapted to support a motor at its outer extremity, a gear on the inner end of said forearm concentric with the pivot connecting said arm, and a pivoted rod provided with a rack meshing with the gear of said forearm, substantially as and for the purpose described.

3. In a folding dental-engine wall-bracket, the combination of a stationary wall-plate, a bracket-plate having horizontal turning connection with said wall-plate, a main arm pivoted to said bracket-plate to swing in a vertical plane, a forearm pivoted to the outer end of said main arm and capable of swinging in the same plane with the main arm, a gear on the inner end of said forearm concentric with the pivot connecting said arm, and a rod pivoted to said bracket-plate below the pivotal connection of said main arm with said bracket-plate, said rod having a rack which meshes with said gear, substantially as and for the purpose described.

4. In a folding dental-engine wall-bracket, the combination of a main arm pivoted to swing vertically, a forearm pivoted to the outer end of said main arm, a gear on the inner end of said forearm, a rod pivoted at its inner end and provided with a rack meshing with said gear, and a hanger depending from the pivot connecting the main and fore arm, said hanger having a bearing for maintaining the rack of said rod in engagement with said gear, substantially as and for the purpose described.

5. In a folding dental-engine wall-bracket, the combination of a bracket-arm provided with a tubular or socketed outer extremity, a forked carrier having swiveling connection with said bracket-arm by means of its spindle fitted to turn in the socket of said arm, and a motor suspended between the forks of said carrier by horizontal transverse, substantially as and for the purpose described.

6. In a folding dental-engine wall-bracket, the combination of a bracket-arm, a forked carrier at its outer extremity, a motor suspended between the forks of said carrier, horizontal transverse between said forks and said motor, and coiled springs interposed between said transverse and said motor for the purpose of absorbing the vibration of the motor, substantially as described.

696,546. TELESCOPING WICKET FOR COUNTER GUARD. WALLA RICHARD R. BROWNE, Brooklyn, N. Y. Filed May 8, 1901. Serial No. 60,225. (No model.)

Claim.—In a counter-wicket, the combination of a grated window having a series of tubes and a cross-bar, a sliding wicket comprising a lower cross-bar and a series of rods secured thereto adapted to slide within the window-tubes, a counter, and a bed-rail upon the counter projecting into the window-opening at each side sufficiently to support above the counter the ends of the sliding wicket.

696,547. INTERNAL-COMBUSTION ENGINE. PERCY BURN, Hellybank, Bethwell, Scotland. Filed Aug. 12, 1901. Serial No. 72,525. (No model.)

Claim.—1. In an internal-combustion engine, the combination, with a low-pressure cylinder, of two high-pressure cylinders of smaller diameter than the low-pressure cylinder and arranged axially in line with it and at opposite ends thereof, an exhaust-pipe connecting the working ends of the high-pressure cylinders, and a passage connecting the said exhaust-

pipe with the working end of the said low-pressure cylinder, substantially as set forth.

2. In an internal-combustion engine, the combination, with a low-pressure cylinder, of two high-pressure cylinders of smaller diameter than the low-pressure cylinder and arranged axially in line with it and at opposite ends thereof, an exhaust-pipe connecting the working ends of the high-pressure cylinders, a passage connecting the said exhaust-pipe with the working end of the said low-pressure cylinder, an air-pipe connected with the working ends of the said high-pressure cylinders, and a passage connecting the said air-pipe with the opposite end of the said low-pressure cylinder, substantially as set forth.

696,548. ASSAYING-FURNACE. ALBERT C. CALKINS, Los Angeles, Cal., assignor to Frederick W. Brown, Los Angeles, Cal. Filed Feb. 4, 1901. Serial No. 64,940. (No model.)

Claim.—1. The improved assaying-furnace comprising a combustion-chamber having a main top flue, a muffle arranged horizontally in said chamber and having its front end open, and its rear end provided with an air-inlet and a device for regulating admission of air thereto, means for temporarily closing the front end of the muffle, and a supplemental flue or passage leading up from each end of the muffle, substantially as shown and described.

2. The improved assaying-furnace comprising a combustion-chamber having a main top flue, a muffle having its front end open, a supplemental flue or passage leading up from each end of the muffle, and a removable plug adapted for closing both the muffle and said passage, substantially as shown and described.

3. The improved assaying-furnace, comprising a combustion-chamber having a main escape-flue and a bonnet therefor, a muffle which traverses the said chamber and is open at each end, passages in the side walls of the furnace which communicate with the muffle, a passage leading upward from one end of the muffle and connecting with the main flue, a plug for closing the passage and the adjacent end of the muffle, and a valve for closing the opposite end of the muffle, substantially as shown and described.

4. The improved assaying-furnace comprising a central combustion-chamber, having a fire-opening, a muffle which traverses the chamber above each opening, double-chambers located on each side of the main chamber, and lateral passages connecting the three chambers, the latter being provided with removable covers, substantially as shown and described.

696,549. CONNECTING DEVICE. JOHN R. CARTER, Augusta, Ky., assignor to Ernst H. Hummel, Cincinnati, Ohio. Filed Aug. 7, 1901. Serial No. 71,907. (No model.)

Claim.—1. In a pinion connection, the combination of two pinions and a shaft, double hooks on one pinion spaced apart and adapted to receive the shaft, a single hook on the other pinion adapted to be disposed on the shaft between the double hooks, and a locking-pin on one of the double hooks to engage the single hook and lock all of the hooks on the shaft when either of said hooks is moved out of the position which permits the placing of said hooks on the shaft.

2. In a pitman connection the combination of two pitmen and a shaft, double hooks on one pitman spaced apart and adapted to receive the shaft, a single hook on the other pitman adapted to be disposed on the shaft between the double hooks, a locking-pin at the free end of the double hooks to engage the single hook and lock all of the hooks on the shaft when either of said hooks is moved out of the position which permits the placing of said hooks on the shaft.

3. In a pitman connection, the combination of two pitmen and a shaft, double hooks on one pitman spaced apart and adapted to receive the shaft, a single hook on the other pitman adapted to be disposed on the shaft between the double hooks, and a locking-pin connecting the free ends of the double hooks to extend over the outer face of the single hook and lock all of the hooks on the shaft when either of said hooks is moved out of the position which permits the placing of said hooks on the shaft.

4. In a pitman connection the combination of two pitmen and a shaft, double hooks on one pitman spaced apart and adapted to receive the shaft, a single hook on the other pitman adapted to be disposed on the shaft between the double hooks, and means on one of the double hooks to extend over the outer face of the single hook and lock all of the hooks on the shaft when either of said hooks is moved out of the position which permits the placing of said hooks on the shaft.

696,550. CAR-SOLDERING MACHINE. JAMES D. COX and FRANK A. COX, Bridgeport, N. J.; said Cox assignors to Cox Brothers & Company, Bridgeport, N. J. Filed Jan. 14, 1901. Serial No. 48,794. (No model.)

Claim.—1. In a soldering-machine, the combination of soldering-tool, solder-delivering device, and a shield movable to and from a position between the tools and said device, substantially as and for the purpose described.

2. In a soldering-machine, the combination of soldering-tool, solder-delivering device, a shield and means for moving the latter to and from a position between the tools and said device, substantially as and for the purpose described.

3. In a soldering-machine, the combination of soldering-tool, solder-delivering device, a shield, and automatically-operated means to move the latter to and from position between the tools and said device, substantially as and for the purpose described.

4. In a soldering-machine, the combination of soldering-tool, solder-delivering device, movable to and from the tools, and a rising and falling work-support that operates said device, substantially as and for the purpose described.

5. In a soldering-machine, the combination of soldering-tool, solder-delivering device, and guiding mechanism, means for moving the guiding mechanism to and from the tools, and a rising and falling work-support that operates said means, substantially as and for the purpose described.

6. In a soldering-machine, the combination of solder-delivering mechanism, means for operating the same, comprising a travelling band, a bar, adapted to actuate the band, means for moving the bar into and out of position for actuating the band, and means for moving the bar to cause it to move said band, substantially as and for the purpose described.

7. In a soldering-machine, the combination of solder-delivering mechanism, means for operating the same, comprising a travelling band, a band-gripping device, a bar, means for moving said bar into and out of engagement with said device, and means for moving the bar in a direction to move the band through said gripping device, substantially as and for the purpose described.

8. In a soldering-machine, the combination of solder-delivering mechanism, means for operating the same comprising a chain, a chain-engaging device, a bar, means for moving said bar into and out of engagement with the chain-engaging device, and means for moving said bar whereby it may move the chain, substantially as and for the purpose described.

9. In a soldering-machine, the combination of solder-delivering mechanism, means for operating the same comprising a chain, a chain-engaging device, a bar, means controlled by the presence of the tray for engaging said bar and chain-engaging device, and bar-operating mechanism, substantially as and for the purpose described.

10. In a soldering-machine, the combination of a frame having side pieces, a work-support, soldering-tool, and a frame carrying said tools above the work-support, pivoted between the frame sides on a horizontal axis, substantially as and for the purpose described.

11. In a soldering-machine, the combination of a frame having side pieces, a work-support, soldering-tool, and a frame carrying said tools above the work-support, pivoted between the frame sides on a horizontal axis, a shaft and connection between the same and the tool-carrying frame for swinging said tool-carrying frame, substantially as and for the purpose described.

12. In a soldering-machine, the combination of a holder or receptacle for material to be used for soldering, means for moving the same horizontally, device for delivering said material to the same, actuating means for said device, and an operating device for said actuating means movable into and out of position to engage the same having a part in the horizontal path of the same, for engagement by the same to move said device into position to engage said actuating means, substantially as and for the purpose described.

13. In a soldering-machine, the combination of an acid or flux receptacle, dipper, and means for actuating the latter, controlled by the horizontal travel of the same, substantially as and for the purpose described.

14. In a soldering-machine, the combination of an acid or flux receptacle, dipper, a movable work-support, means independent of the work to operate the dipper, and means actuated by the work to control the latter, substantially as and for the purpose described.

15. In a soldering-machine, the combination of an acid or flux receptacle, dipper, means independent of the work for operating the dipper, and means whereby the horizontal travel of the work controls said dipper-operating means, substantially as and for the purpose described.

16. In a soldering-machine, the combination of a device to be operated, a rotary and longitudinally-movable shaft, an arm carried by the latter adapted to be placed into and out of operative relation to said device, means to move the shaft longitudinally, and work-engaged means for turning it, substantially as and for the purpose described.

17. In a soldering-machine, the combination of an acid or flux receptacle, dipper, a rotary and longitudinally-movable shaft, an arm carried by the latter adapted to be placed into and out of operative relation to the dipper, means to move the shaft longitudinally, and work-engaged means for turning it, substantially as and for the purpose described.

18. In a soldering-machine, the combination of an acid or flux receptacle, dipper, a longitudinally-movable rod connected to the dipper, a rotary and longitudinally-movable shaft, an arm on the latter movable into and out of position in line with said rod, means to move the shaft longitudinally, and an arm by which it may be turned, substantially as and for the purpose described.

19. In a soldering-machine, the combination of an acid or flux receptacle, dipper, a longitudinally-movable rod connected to the dipper, a rotary and longitudinally-movable shaft, an arm on the latter, to operate with said rod, a cam-actuated lever to move said shaft longitudinally, and a cam-actuated means for turning it, substantially as and for the purpose described.

20. In a soldering-machine, the combination of a frame, soldering mechanism, a bed, arms pivoted to the frame and to the bed, and means for raising and lowering the bed, substantially as and for the purpose described.

21. In a soldering-machine, the combination of soldering mechanism, a movable solder-guide, a rising and falling work-support, and a lever connected with the solder-guide and in the path of a part carried by the work-support, substantially as described.

22. In a soldering-machine, the combination of soldering mechanism, a movable solder-guide, a rising and falling work-support, and a lever connected with the solder-guide and in the path of a part carried by the work-support, substantially as described.

23. In a soldering-machine, the combination of soldering mechanism, a movable solder-guide, a rising and falling work-support, and a lever connected with the solder-guide and in the path of a part carried by the work-support, substantially as described.

24. In a soldering-machine, the combination of soldering mechanism, a movable solder-guide, a rising and falling work-support, and a lever connected with the solder-guide and in the path of a part carried by the work-support, substantially as described.

25. In a soldering-machine, the combination of soldering mechanism, a movable solder-guide, a rising and falling work-support, and a lever connected with the solder-guide and in the path of a part carried by the work-support, substantially as described.

696,551. HOLDING APPARATUS. CALVIN E. DAVIS, South Bend, Ind., assignor to South Bend Iron Works, South Bend, Ind. Filed Sept. 24, 1901. Serial No. 76,266. (No model.)

Claim.—1. The combination with a molding apparatus, of a nozzle mounted on the apparatus to oscillate, means for conveying air to said nozzle and means also mounted on the apparatus and connected with said nozzle for imparting an oscillatory motion to the latter.

2. The combination with the top plate of a mold and a pressure-plate, of a nozzle mounted on said top plate and adapted to discharge upon the pressure-plate, a valve for said nozzle, and device mounted on the top plate and connected with said nozzle for oscillating it.

3. The combination in a molding-machine, of a nozzle, means for conveying air to the nozzle, a valve for controlling the supply of air, a lever and device co-operating with said lever to operate the valve and oscillate the nozzle.

4. The combination in a molding apparatus, of an oscillatory nozzle, means for conveying air thereto, a controlling-valve and means for operating said valve and oscillating the nozzle.

5. The combination in a molding apparatus, of an oscillatory nozzle, means for supplying air thereto, a valve, means for opening said valve and oscillating the nozzle and means for returning the nozzle and closing the valve.

6. In a molding apparatus the combination with a nozzle, means for moving it and means for conveying air to it, of a valve for controlling the air-supply, a spring holding the valve normally closed and means for releasing said spring to open the valve when the means for moving the nozzle are operated.

7. In a molding-machine, the combination of a shaft, a diagonal arm on said shaft, a nozzle connected to said arm, means for oscillating said shaft and means for conveying air to said nozzle.

8. In a molding apparatus, the combination with a shaft and a diagonal arm projecting therefrom, of a nozzle secured to said arm, means for conveying air to said nozzle, a rock-shaft connected with the first-mentioned shaft for operating it, and means for operating the rock-shaft.

9. In a molding apparatus, the combination of an upright shaft, a nozzle carried thereby, a crank-arm on said shaft, a rock-shaft, a crank-arm on the rock-shaft, a pitman connecting said crank-arms, and means for operating the rock-shaft.

10. In a molding apparatus, the combination of an oscillatory shaft, a nozzle carried thereby, means for conveying air to the nozzle, an air-controlling valve, a lever, means co-operating with said lever to operate the valve, and device intermediate of the lever and oscillatory shaft for operating the latter.

11. In a molding apparatus, the combination with an oscillatory nozzle and means for conveying air thereto, of a valve for controlling the air-supply, a lever, device intermediate of said lever and the nozzle and device intermediate of the lever and valve for opening the latter and shutting the nozzle when the lever is thrown forwardly, and a spring for returning the nozzle and lever and closing the valve.

12. In a molding apparatus, the combination with an oscillatory nozzle, an air-supply pipe and a valve in said pipe, of a bar on the stem of said valve, having an arm at one end, a spring attached to said bar below the axis of the valve, and a lever adapted to engage the arm on the bar and raise the connection of the spring to the latter above the axis of the valve to permit the spring to open the valve.

13. In a molding apparatus, the combination with an oscillatory nozzle, and means for supplying air thereto, of a rock-shaft for oscillating the nozzle, a guide-arm secured to said rock-shaft, a shoulder on said arm and a lever pivoted to said lever below said shoulder.

14. In a molding apparatus, the combination of an oscillatory nozzle, a pipe for conveying air thereto, and a valve in said pipe, of a rock-shaft, device intermediate of the rock-shaft and nozzle for operating the latter, an arm secured to the rock-shaft, a shoulder on said arm, a lever pivoted to the arm and adapted to engage the shoulder thereon, a bar on the stem of the valve, and a pin on the lever to engage said bar.

696,552. DRAFT OR FOLD SUPPORT. BENJAMIN S. DRENNAN, Chicago, Ill. Filed Dec. 4, 1901. Serial No. 94,721. (No model.)

Claim.—A draft-support consisting of a vertical plate, the lower end of which is adapted to be secured to the fixed end of the coupling, the upper portion formed with a vertical chamber, and an arm having a longitudinal slot engaging a pivot-pin in said chamber and adapted to rest in said chamber when not in use and a spring secured in said chamber and adapted to hold said arm in its rest or chamber, substantially as set forth.

696,553. PNEUMATIC STACKER. DANIEL DOW, Grand Port, N. D. Filed Oct. 24, 1901. Serial No. 79,941. (No model.)

Claim.—1. In a pneumatic stacker, the combination of a main wind-tube, a fan, a shaft-floor disposed above the fan, a main air-dust, a shaft air-dust having an inlet near the lower part of the fan and a throat located at the bottom of the shaft-floor, substantially as described.

2. In a pneumatic stacker, the combination of a main wind-tube, a fan located at the lower portion thereof, a shaft-floor disposed above the fan, a main air-dust, and a shaft air-dust having an inlet near the lower part of the fan and provided with an adjustable throat.

3. In a pneumatic stacker, the combination of a main wind-tube, a shaft-floor located therein, a fan located at the lower portion thereof, a main air-dust and a shaft air-dust connected with the fan near the lower portion thereof, the throat or outlet of the shaft-dust having one of its walls flexible and provided with means for adjustably setting the same.

4. In a pneumatic stacker, the combination of a main wind-tube, a shaft-floor heated therein, a fan located at the lower portion thereof, a main air-dust on the under side of the shaft-floor, a shaft-dust above the shaft-floor and a shaft-deflector diagonally over the shaft-floor.

5. In a pneumatic stacker, the combination of a main wind-tube, a shaft-floor disposed intermediate thereof, a diagonally-disposed shaft-

deflector disposed upon the chaff-floor and a fan located near the lower end of the chaff-floor and adapted to deliver air to both sides thereof.

6. In a pneumatic stacker, the combination of a main wind-tube, a chaff-floor disposed intermediately thereof, a diagonally-disposed conveyer chaff-deflector upon the chaff-floor and a fan located near the bottom of the chaff-floor.

696,554. SUPPORTING-TOOL. ALPH A T. DUNLEY, Brooklyn, Mass. Filed Jan. 20, 1901. Serial No. 46,315. (No model.)

Claim.—1. The combination in a supporting-tool of jaws for engaging the beam, levers for compressing the jaws, a locking device for holding the jaws in engagement with the beam, a cable or chain extending from arm to arm with a bearing or chair mounted upon the cable and means for adjusting the work substantially as shown and described.

2. The combination in a supporting-tool of jaws and arms operating in transverse planes, a locking-dog, or pawl and ratchet for locking the bits on the beam, a pulley mounted upon one of the arms and an adjustable hook mounted upon the other arm for connecting a cable or chain to the tool substantially as and for the purpose set forth.

3. In a supporting-tool, substantially as shown, a locking dog or pawl pivoted to the arm of the tool, a slotted pivot-bolt rigidly fixed in the seat of pawl and passing through the arm of the tool, a spring inserted in the slot of the bolt and adapted to engage the under part of the arm and to hold the teeth of the pawl in engagement with the ratchet on the jaw of the tool substantially as shown and described.

4. In a supporting-tool as arm substantially as shown, provided with a boss upon the end of the same, a cup-shaped cavity in the upper surface of the boss, a triangular slot in the bottom of the cup, or cavity, a hook, having a threaded staff with threaded nut and hemispherical washer, mounted in said cavity, substantially as and for the purpose described.

5. In a supporting-tool substantially as shown in combination with the arm thereof, having a boss or enlargement at the end of the arm and a vertical slot in the boss or enlargement, a pulley provided with an annular groove adapted to carry a cable or chain, mounted in the slot, substantially as shown and described.

6. A supporting-tool comprising a pair of hooks pivoted together near their angle of curvature with self-adjusting jaws mounted upon the upper part of the hooks, a pawl mounted upon an arm of the tool, a ratchet upon the external face of one of the hooks, a spring mounted in the pivot-bolt of the pawl and adapted to hold the pawl in engagement with the ratchet and lock the jaws of the tool in engagement with the beam, a hook provided with a threaded staff and nut mounted upon one arm, and a pulley mounted upon the other arm of the tool, a cable or chain connecting the hook and pulley together and a chain mounted upon the cable and adapted to support the work substantially as shown and described.

696,555. SULKY-LISTER. GWAY E. HUGHMAN, Dallas, Tex. Filed Oct. 24, 1901. Serial No. 73,444. (No model.)

Claim.—1. The combination of a sulky-frame, a plow connected thereto, to open a furrow, means, carried by said frame, to raise and lower the plow, a seed-dropping mechanism, in rear of the plow, pivotally connected thereto, and having supporting-disk to cover the seeds in the furrow, and a connection including a spring, between the plow and the seed-dropping mechanism, to depress the latter, the said spring also supporting the said seed-dropping mechanism when the latter is raised, substantially as described.

2. In a sulky-lister, the combination with a lister-plow, of a seed-dropping mechanism having supporting revolvable disks, and disposed in rear of the plow, said seed-dropping mechanism having a frame pivot-

ally connected to said lister-plow, and a spring connection between the latter and said frame, to depress said seed-dropping mechanism, for the purpose set forth, substantially as described.

3. The combination with a plow, of a seed-dropping mechanism having supporting revolvable elements and a forwardly-extending frame, the latter being pivotally connected to said plow, and a spring connection between said frame and said plow to depress said seed-dropping mechanism, substantially as described.

4. The combination with a plow, of a seed-dropping mechanism having supporting revolvable elements and a forwardly-extending frame, the latter being pivotally connected to said plow, a pair of overlapping link-bars respectively connected to said frame and to said plow, and a spring connection between the said link-bars, substantially as described.

5. The combination with a plow, of a seed-dropping mechanism having supporting revolvable elements and a forwardly-extending frame, the latter being pivotally connected to said plow, a link-bar connected to the latter, a link-bar adjustably connected to said frame, said link-bars overlapping each other, and a spring connecting said link-bars, the tension of the said spring being varied by adjusting said adjustably-connected link-bar, substantially as described.

696,556. DISE-WASHER. IDA REYER, Bismarck, Tex. Filed July 20, 1901. Serial No. 68,125. (No model.)

Claim.—1. A device of the kind described comprising a tank divided into two compartments, one of said compartments being adapted to receive water and having a rotary beater or agitator journaled therein, the other compartment having an adjustable drain or rest upon which the dishes are placed, substantially as shown and described.

2. A device of the kind described consisting of a tank divided transversely into two compartments, one of the compartments being intended to receive water and having a rotary beater or agitator journaled therein.

and a rest or drain arranged in the other compartment, said rest or drain being hinged at one end and provided with flaps at the opposite end to engage beads arranged at the end of the tank, substantially as shown and described.

696,557. AUTOMATIC SHUT-LOCK. FRANK CHASE, Valparaiso, Cal. Filed Sept. 20, 1901. Serial No. 73,175. (No model.)

Claim.—1. In a shut-locking device, the combination of a plate adapted to be secured to the lower end of a window, of a bell-crank lever fulcrumed on said plate, a fulcrum-pin integral with said lever, a groove on said plate in which said pin rests and in which it is maintained, caps for said fulcrum-pin, notches in said caps and bosses on the plate fitting said notches whereby the caps are held in place, one arm of said lever weighted and adapted to have a tilting movement, and a stop upon the upper end of the window with which said weighted arm engages when the window is closed.

2. In a shut-locking device, the combination with the upper and lower sashes of a window, of a plate secured on the top of the lower sash, and adapted to extend beyond the outer edge of said sash, said plate having a transverse groove in its upper surface, and having a projection or wedge on the under side of said extension, a bell-crank lever fulcrumed on said plate and having a weighted tilting arm, said lever having on its under side a transversely-extending projection to fit the groove of the plate and form a pivotal connection therewith, and a slotted angle-plate upon the upper sash, secured in relation to said first-named plate and lever, with which the said weighted arm and wedge are adapted to engage when the window is closed to respectively lock and to draw the sashes together.

696,558. LIFTING-JACK. LAMON E. GOSWORTHY, Arlington, N. J., assignor of one-half to Joseph B. Ray, Newark, N. J. Filed June 3, 1901. Serial No. 68,792. (No model.)

Claim.—1. In a lifting-jack, the combination with the hollow base provided with a retaining-part, of a vertical bar adapted to slide vertically in said base and provided with teeth to engage said part, a verti-

cally-sliding head mounted on said bar, and provided with laterally-projecting friction-rolls, and a lever pivoted to said bar, and adapted to hang normally below its point of pivoting, said lever being provided with bifurcated cam portions for engaging said friction-rolls, substantially as described.

2. In a lifting-jack, the combination with the vertical bar, of a sliding head engaging the upper part of the same, a lever provided with curved or cam bifurcated arms pivoted at their extremities to said bar, whereby said lever normally hangs below its point of pivoting and friction-rolls projecting laterally from said head and engaging said curved or cam arms, whereby the upward movement of said lever will raise said head, substantially as described.

3. In a lifting-jack, the combination with the vertical bar, of a sliding head mounted on the upper end of said bar, said head being provided at its upper end with laterally-extending centering-arms, provided on their upper faces with grooves or depressions, said head being provided at its lower end with laterally-extending friction-rollers, a lever provided with bifurcated curved or cam portions, pivoted at their extremities to said vertical bar, and engaging said friction-rollers, said lever normally hanging downward from its pivotal connection with said bar, whereby the upward movement of said lever will raise said head, substantially as described.

696,559. GATE. BRAD CHAMBERLAIN, Quincy, Ill., assignor of one-half to C. C. Payne, Quincy, Ill. Filed Dec. 2, 1901. Serial No. 68,907. (No model.)

Claim.—1. A tilting and folding gate, comprising a hollow housing open on one side, pivotal pins mounted in the opposite faces of said housing, strips mounted on said pins, a curved segment secured to one of said strips, a spring fulcrumed at its lower end, to the lower one of said strips, a strap fastened to the upper end of said segment and having connection with the upper end of the spring, and means connected to the gate, for automatically opening and closing the top of said housing, as set forth.

2. A tilting gate, comprising a housing open on one side, strips pivotally mounted within said housing, spring connections between the pivotal ends of said strips, a hinged top to said housing, and pivotal link connection between said top and one of said strips, as set forth.

696,560. DIVING APPARATUS. JAMES GULMARTIN, Boston, Mass. Filed June 2, 1902. Serial No. 719,392. (No model.)

Claim.—1. In an instrument for the purpose specified, a combination of two cooperating members, the first of which consists of three parts two of the parts being so joined that their inner edges are perpendicular to each other and being so attached to a plane surface of the third part that the vertex of a right angle formed by the junction of the said two parts is vertically over the center of a circular arc upon the said surface, the second of which members, being not attached to the first member, has two end edges adapted to engage and slide upon the perpendicular edges of the said second two parts of the first member and is of a length between the said end edges not greater than the distance between the outer ends of the said second two parts, all substantially as described.

2. In an instrument for the purpose specified, a combination of two cooperating members, the first of which consists of two parts joined together in such manner that their inner edges are perpendicular to each other, the lower surface of one of the parts being in a different plane from the lower surface of the other part whereby when one part is placed in contact with a plane surface there is a free space under the other part sufficient for the necessary movements of the second member, the second member of which has two end edges adapted to engage and slide upon the perpendicular edges of the first member, a projection beyond one of these edges adapted to operate in said free space, an indicating-mark midway of the end edge and in a plane passing through the same, and is beveled at and for a short distance on either side of the indicating-mark.

3. In an instrument for the purpose specified, a combination of two cooperating members, the first of which consists of two parts rigidly fastened together in such manner that their inner edges are perpendicular to each other, the second of which consists of a member having two end edges adapted to engage and slide upon the perpendicular edges of the first member and having an indicating-mark midway of the end edge and in a plane passing through the same and being beveled at and for a short distance on either side of the indicating-mark.

4. In an instrument for the purpose specified, a combination of two cooperating members, the first of which consists of three parts two of the parts being so joined that their inner edges are perpendicular to each other and being so attached to a plane surface of the third part that the vertex of a right angle formed by the junction of the said two parts is vertically over the center of a circular arc upon the said surface, the second of which members, being not attached to the first member, has two end edges adapted to engage and slide upon the perpendicular edges of the said second two parts of the first member and has an indicating-mark midway between the said end edges and in the same plane therewith and is of such a length between these edges that it may be kept in contact with both of the said second two parts at these edges while it is retained upon the said plane surface.

5. In an instrument for the purpose specified, a combination of two cooperating members, the first of which consists of two parts joined together in such manner that their inner edges are perpendicular to each other, the lower surface of one of the parts being in a different plane from the lower surface of the other part whereby when one part is placed in contact with a plane surface there is a free space under the other part sufficient for the necessary movements of the second member, the second of which members has two end edges adapted to engage and slide upon the perpendicular edges of the first member and has a projection beyond one of these edges adapted to operate in said free space and said second member is beveled for a short distance midway between said end edges.

6. In an instrument for the purpose specified, a combination of two cooperating members, the first of which consists of two parts joined together in such manner that their inner edges are perpendicular to each other, the second of which consists of a member having two end edges adapted to engage and slide upon the perpendicular edges of the first member and being beveled for a short distance midway between said end edges.

7. In an instrument for the purpose specified, a combination of two cooperating members, the first of which is a square so constructed that it may be properly positioned in relation to a circular arc upon a plane surface, the second of which is a rule having two end edges outside of the plane of its end face perpendicular to and in the same plane with a longitudinal edge of this face, and being beveled from the said longitudinal edge for a short distance midway between the said end edges at an angle to the under face less than the angle of the last-mentioned plane thereto, all substantially as described.

8. In an instrument for the purpose specified, a combination of two cooperating members, the first of which consists of two parts rigidly fastened to a plane surface of a third part the said two parts being so placed that their inner edges are perpendicular to each other, the second of which consists of a member having two end edges adapted to engage and slide upon the perpendicular edges of the said second two parts of the first member and having an indicating-mark midway of the end edge and in a plane passing through the same.

9. The combination of a square and a member having a plane surface provided with a circular arc, the said square being attached to the

said plane surface so that the vertex of an inner right angle formed by the junction of the square's arms is directly over the center of the said arc, with a detached rule adapted for its combined use with the square and of a length between two end edges thereof equal to twice the radius of the arc, all substantially as described.

10. A rule, having two end edges outside of the plane of its under face perpendicular to and in the same plane with a longitudinal edge of this face, and having a midway mark between the said end edges upon the said longitudinal edge, and having a projection beyond one of the said end edges continuing the line of the said longitudinal edge its uppermost face being lower than the top of the said end edge, all substantially as described and for the purpose specified.

11. A detached rule having the form of two rectangular parallelepipeds of different lengths united laterally at longitudinal faces of the same width so that an end face of one is level with and in the same plane with an end face of the other, and having an indicating-mark on a longitudinal edge of the longer parallelepiped at a distance from the said end face equal to half the length of the shorter parallelepiped, all substantially as described and for the purpose specified.

12. In an instrument for the purpose specified, a combination of two cooperating members, the first of which consists of two parts immovably attached to a plane surface and so placed that their inner edges are perpendicular to each other, the second of which consists of a member having two end edges adapted to engage and slide upon the perpendicular edges of the first member and having an indicating-mark midway of the end edge and in a plane passing through the same and being beveled at and for a short distance on either side of the indicating-mark.

13. The combination, with a rule suitably constructed, of a square and another suitable object, the two being immovably attached at a plane surface of the latter so that the vertex of an inner right angle formed by the junction of the square's arms is directly over the center of a circular arc upon the said surface, and the square being so constructed that there is a free space under one of its arms, all substantially as described.

14. A square attached to a plane surface of another suitable object in such manner that the vertex of a right angle formed by the junction of its arms is directly over the center of a circular arc upon said surface, and so constructed that there is a free space between the under surface of one of its arms and the said plane surface, all substantially as described and for the purpose specified.

15. In an instrument for the purpose specified, a portion thereof consisting of three parts, two of these parts being joined together so that their inner edges are perpendicular to each other, and the said two parts being attached to a plane surface of the third part so that the vertex of an inner right angle formed by their junction is directly over the center of a circular arc upon the said surface and so that a point in the same line with one of the said inner edges and in an edge of one of the said second two parts beyond the said vertex is directly over the center of another circular arc upon the said surface, all substantially as described.

16. A rule, having two end edges outside of the plane of its under face perpendicular to and in the same plane with a longitudinal edge of this face, and being beveled from the said longitudinal edge for a short distance midway between the said end edges at an angle to the under face less than the angle of the last-mentioned plane thereto, and having a mark on the said longitudinal edge indicating the middle-distance point between these end edges, all substantially as described and for the purpose specified.

17. A detached rule having two end edges perpendicular to and in the same plane with a longitudinal edge thereof, and having an indicating-mark midway between the said end edges and in the same plane therewith, and being beveled from the said longitudinal edge for a short distance midway between the said end edges at an acute angle to the rule's face in the said plane, and having a projection beyond one of the said end edges less in thickness than the rule, all substantially as described and for the purpose specified.

18. A rule, having two end edges outside of the plane of its under face perpendicular to and in the same plane with a longitudinal edge of this face, and being beveled from the said longitudinal edge for a short distance midway between the said end edges at an angle to the under face less than the angle of the last-mentioned plane thereto, all substantially as described and for the purpose specified.

19. A detached rule having two end edges perpendicular to and in the same plane with a longitudinal edge thereof, and being beveled from the said longitudinal edge for a short distance midway between said end edges, and having a projection beyond one of these edges less in thickness than the rule, all substantially as described and for the purpose specified.

20. For the purpose specified, a detached rule having a shoulder between its ends, the said shoulder and one of the ends being each provided with an edge perpendicular to and in the same plane with a longitudinal edge of the rule, and the said rule being beveled from the said longitudinal edge for a short distance midway between the line of the said shoulder edge and the said end edge, all substantially as described.

21. For the purpose specified, a detached rule having a shoulder at a distance from one end of the rule not less than one-third of the rule's length, the said shoulder and one end of the rule being each provided with an edge perpendicular to and in the same plane with a longitudinal edge of the rule, and the said rule having an indicating-mark midway between the line of said shoulder edge and the said end edge and in the same plane therewith and being beveled at an acute angle to the rule's face in the said plane for a short distance midway between the line of the said shoulder edge and the said end edge.

22. In an instrument for the purpose specified, a portion thereof consisting of three parts, two of the parts being so joined together that their inner edges are perpendicular to each other, and the said two parts being so attached to a plane surface of the third part that the vertex of an inner right angle formed by their junction is directly over the center of a circular arc upon the said surface and that there is a free space under one of the said two parts, all substantially as described.

23. In an instrument for the purpose specified, a portion thereof consisting of three parts, two of the parts being so joined together that their inner edges are perpendicular to each other, and being so attached to a plane surface of the third part that the vertex of an inner right angle formed by their junction is directly over the center of a circular arc upon the said surface, all substantially as described.

24. The combination of a suitable rule with a cooperating member, this member consisting of two parts joined together in such manner that their inner edges are perpendicular to each other, and one of these parts being so graduated as to indicate at its point of contact with the rule three times the angle of the rule's inclination to the other part when the rule is placed obliquely between the said parts so as to be in contact with both, all substantially as described.

25. A rule, having two end edges perpendicular to its under face and in the same plane with a longitudinal edge of this face, and being beveled from the said longitudinal edge for a short distance midway between the said end edges, all substantially as described and for the purpose specified.

696,561. DRESS-SKIRT LIFTER. JOHN HANSEN and KATHERINE M. HANSEN, Tacoma, Wash. Filed Dec. 12, 1901. Serial No. 95,547. (No model.)

Claim.—A skirt-lifter of the character described, comprising a series of tapes united at their upper ends and spread apart at their lower ends and adapted to be attached to the skirt at their lower ends and at their upper ends, and a buckle consisting of two disks arranged above the cords, one of which is adapted to be supported by the belt or waistband of the skirt and is provided with a loop, and the other of which is adapted to be secured to the skirt below the other part and provided with a hook to engage the loop, substantially as set forth.

696,562. WARNING-MACHINE. JOHN R. HARTMAN, Danversport, Iowa. Filed Apr. 17, 1901. Serial No. 95,551. (No model.)

Claim.—1. A device of the class described comprising a central bearing, warning mechanism mounted thereon, and the rods extending radially therefrom and adjustably connected with the central bearing and provided at their outer ends with right clamps arranged to engage the upper edges of a washbasin, substantially as described.

2. A device of the class described comprising a central bearing having threaded apertures, warning mechanism mounted on the central bearing, and the rods provided at their outer ends with clamps having fixed inner and outer jaws, said rods being threaded at their inner ends to engage the apertures of the central bearing, substantially as described.

3. A device of the class described comprising a tub, a central bearing, rods connected with the central bearing and with the tub, an ap-

per having a stem extending through the bearing, a handle arranged at the upper end of the stem and located above the central bearing, and a flexible cover having a central opening to receive the stem, said cover being supported by the rods and being located between the same and the handle, substantially as described.

4. A device of the class described comprising a central bearing, rods extending from the central bearing and provided with means for engaging the upper edges of a washbasin, a sleeve arranged within the bearing and supported by the same and provided at its top with a recess or seat, an agitator having a stem secured to the sleeve and extending upward therefrom, and a handle detachably fitted on the stem and arranged in the seat of the sleeve, substantially as described.

5. A device of the class described comprising a central bearing, means for supporting the same, a sleeve arranged in the bearing and provided with a head resting on the bearing and having upwardly-extending flanges to form a seat, said sleeve being also provided with inwardly-extending legs, an agitator having a stem secured to the sleeve and provided with recesses to receive the legs thereof and extending upward from the top of the sleeve, and a handle arranged between the flanges of the sleeve and having an opening to receive the extension of the stem, substantially as described.

696,563. CALF-WEANER. JOHN J. HENRI, Waco, Tex. Filed Dec. 11, 1901. Serial No. 95,511. (No model.)

Claim.—1. A device of the character specified, comprising attaching means, fixed side prickers, and hinged front prickers.

2. A device of the character specified, comprising attaching means, side and center pricks, fixed prickers disposed adjacent to the side pricks, and hinged prickers arranged on each side of the center pricks.

3. A device of the character specified, comprising a nose-strap, side and center pricks secured thereto, rods secured to the said pricks, fixed prickers secured to the rods adjacent to the side pricks, and hinged prickers mounted on the rods on each side of the center pricks.

4. A device of the character specified, comprising a nose-strap, side and center pricks secured thereto, curved rods associated with the pricks, fixed prickers arranged adjacent to the side pricks, and having one terminal end and their intermediate portions secured to the rods, and movable prickers disposed on each side of the center pricks, and having their intermediate portions secured about one of the rods and their terminals diverged and overlapping the other rod.

696,564. COMPUTING MEASURING-CARKET. EDWIN HERRMANN, OMAHA, IOWA, assignor of two-fifths to George W. Herrmann, Omaha, Iowa. Filed Apr. 26, 1901. Serial No. 97,000. (No model.)

Claim.—1. An improved measuring-carket, comprising a hopper having an opening in its bottom, a horizontal partition some distance beneath the hopper and having an opening cut of vertical alignment with the opening in the hopper, a measuring-chamber open at its top and bottom and slidingly mounted between the hopper and partition, a sliding vertical partition in the measuring-chamber, means for adjustably securing said sliding partition in position relative to the measuring-chamber, an indicating-finger fixed to the adjustable partition, and a scale-plate fixed to the machine-frame adjacent to the said finger for the purpose stated.

2. An improved measuring-cabinet, comprising a hopper having an opening in its bottom, a horizontal partition some distance beneath the hopper and having an opening out of vertical alignment with the opening in the hopper, a measuring-chamber open at its top and bottom and slidingly mounted between the hopper and partition and having a longitudinal slot in one side a sliding vertical partition in the measuring-chamber having an end, top, and side piece, said side piece being designed to cover the slot in the measuring-chamber, an indicating-finger fixed to the sliding partition and projecting through said slot in the measuring-chamber, means for adjusting the vertical partition relative to the measuring-chamber, and a scale-plate fixed to the machine-frame to assume a position adjacent to the indicating-finger for the purpose stated.

3. An improved measuring-cabinet, comprising a hopper having an opening in its bottom, a horizontal partition some distance beneath the hopper and having an opening out of vertical alignment with the opening in the hopper, a measuring-chamber open at its top and bottom and slidingly mounted between the hopper and partition and having a longitudinal slot in one side, a handle fixed to the same side, a strip 21 in the measuring-chamber, an adjustable partition in the measuring-chamber comprising a top, end, and side, said top being designed to pass under the strip 21, an indicating-finger fixed to the side of the adjustable partition and passed through the slot in the measuring-chamber, a clamping device connected with the vertical partition and passed through the slot in the measuring-chamber and capable of providing a handle by which the vertical partition may be moved and also providing means for clamping the vertical partition to the measuring-chamber, and a scale-plate having slots in its ends and screws passed through said slots into the body of the cabinet whereby the scale-plate may be detachably and adjustably connected with the said body portion, substantially as and for the purpose stated.

4. An improved measuring-cabinet, comprising a hopper, a horizontal partition beneath the hopper, having an opening therein communicating with the hopper, a second horizontal partition some distance beneath the first, and having an opening out of alignment with the opening in the first partition, a measuring-chamber open at its top and bottom and slidingly mounted between said partitions, said measuring-chamber having a horizontal slot in one side, a strip 21 mounted between the sides of the measuring-chamber near its outer end, a handle 19 secured to the measuring-chamber, a partition comprising the sides 22, top 24, and end 25, said end having a flexible strip, 26 thereon, an indicator fixed to the sliding partition and passed through the slot in the measuring-chamber, means for securely clamping the partition to the measuring-chamber, and a detachable scale-plate on the machine-frame adjacent to the said indicator, arranged and combined substantially in the manner set forth and for the purpose stated.

696,565. TYPE-WRITER CABINET. WILLIAM HERRMANN, Hartman, N. Y., assignor to Herrmann Desk Company, Hartman, N. Y. Filed May 2, 1901. Serial No. 58,694. (No model.)

Claim.—1. The combination of a desk, horizontal guides arranged therein in a backward and forward direction, a base-plate which is slidable in said guides in and out of the desk, rock-arms which are pivoted at their lower ends to said slidable base-plate to swing forward and backward and which take part in the sliding movement of said base-plate, a type-writer platform which is pivotally attached to the upper ends of said

rock-arms and is supported by the latter, a stop on each slidable base-plate which arrests the forward movement of the rock-arms when the latter have passed the desk-center and which holds the rock-arms in their forward position, and means for holding the base-plate from backward movement while the arms are being swung backward, substantially as set forth.

2. The combination of a desk, horizontal guides arranged therein in a backward and forward direction, a base-plate which is slidable in said guides in and out of the desk, rock-arms which are pivoted at their lower ends to the upper face or surface of said slidable base-plate to swing forward and backward and which take part in the sliding movement of said base-plate, and a type-writer platform provided with rearward extensions between which the upper ends of said rock-arms are arranged and to which the rock-arms are pivoted, substantially as set forth.

3. The combination of a desk, horizontal guides arranged therein in a backward and forward direction, a base-plate which is slidable in said guides in and out of the desk, rock-arms which are pivoted at their lower ends to said slidable base-plate to swing forward and backward and which take part in the sliding movement of said base-plate, said rock-arms being arranged one behind the other and consisting each of side bars and connecting transverse braces, and a type-writer platform pivoted to the upper end of the side bars of said rock-arms, said arms occupying a position above the base-plate when the platform is in its retracted position, substantially as set forth.

4. The combination of a desk, a base-plate guided therein and slidable in and out of the desk, a slidable type-writer platform, and means for moving and supporting the same arranged wholly above the top face of said base-plate and supported thereon, said means including front and rear pivoted supporting-arms, substantially as set forth.

5. The combination of a base-plate, a support on which said plate can be moved forward or backward, a type-writer platform arranged above said plate, rock-arms connecting the latter with said platform, a catch by which said base-plate is held in its forward position against backward movement, and a releasing device which is attached to said platform and adapted to release said catch upon lowering the platform, substantially as set forth.

6. The combination of a base-plate, a support on which said plate can be moved forward or backward, a type-writer platform arranged above said plate, rock-arms connecting the latter with said platform, a spring-catch attached to said plate and adapted to hold the latter in its forward position against backward movement, and a releasing-finger which projects downwardly from the platform and releases the catch upon lowering the platform, substantially as set forth.

7. The combination of a base-plate, a support on which said plate can be moved forward or backward, a type-writer platform arranged above said plate, rock-arms connecting the latter with said platform, a holding-down ledge arranged on said platform, and a stop under which said ledge engages when the platform is in its lowered and backward position, substantially as set forth.

696,566. ROTARY WATER-TUBE. ARTHUR S. ENGIN, Kansas City, Mo. Filed May 11, 1901. Serial No. 59,748. (No model.)

Claim.—1. In a water-tube boiler, the combination of a cluster of water-tubes and manifolds to which the same are connected, supports on which the manifolds are rotatably mounted, and means for rotating the same.

2. In a water-tube boiler, the combination with a stationary steam and water drum and a stationary mud-drum, of a cluster of water-tubes and manifolds to which the same are connected, supports on which the same are rotatably mounted, means for rotating the same, and connection between the manifolds and steam and water drum and mud-drum respectively.

3. In a water-tube boiler, the combination of a cluster of water-tubes and manifolds to which the same are connected, of supports for the manifolds, rollers on said supports on which the manifolds rest, and means for rotating the manifolds and water-tubes.

4. In a water-tube boiler, the combination of a cluster of inclined water-tubes and manifolds to which the same are connected, of supports

for the manifolds, rollers on said supports on which the manifolds rest, the rollers on the lower support being provided with flanges for engaging the ends of the manifolds, and means for rotating the manifolds and water-tubes.

5. In a water-tube boiler, the combination of a cluster of water-tubes and manifolds to which the same are connected, supports on which manifolds are rotatably mounted, a gear connected to one of the manifolds, and a worm engaging said gear for rotating the same.

6. In a water-tube boiler, the combination with a furnace, of a cluster of water-tubes and manifolds to which the same are connected, supports on which the same are rotatably mounted, means for rotating the same, a baffle-wall projecting into the furnace-chamber and a division-plate in line with the baffle-wall and through which the tubes pass.

7. In a water-tube boiler, the combination of a cluster of water-tubes and manifolds to which the same are connected, supports on which the same are rotatably mounted, means for rotating the same, and steam and water connections to said manifolds the same comprising a pipe having annular grooves, and a device having annular projections fitting into said grooves.

696,567. CORRUGATED OR LAMINATED MATERIAL. JAMES T. JOHNSON, Knoxville, Tenn. Filed Oct. 20, 1899. Serial No. 735,507. (No specimen.)

Claim.—1. An improved article of manufacture, a laminated body consisting of two or more layers of woven fabric permanently secured together, the warp-threads or lines of strain of each layer being disposed at an angle to the warp-threads or lines of strain of each adjacent layer, whereby each layer is made to check the elasticity of the other, and a top finish or layer of yielding material of a character different from that of the body, substantially as and for the purpose specified.

2. As an improved article of manufacture a combination material in flexible sheet form and consisting of a laminated body composed exclusively of two or more layers of textile fabric of a continuous or subcontinuous weave and similar in dimension, the said layers having both the warp and weft threads constantly remaining in close-woven arrangement and the warp-threads of each layer at an angle to those of the adjacent layer or layers, whereby each layer checks the elasticity of each adjacent layer and the entire laminated structure prevented from drawing in any direction, and a thin layer of yielding material secured to one side only of the body, the entire combination material being apertured at regular intervals.

696,568. SHADE-ROLLER MACHINERY. BENJ. F. KAMM, France. Filed Apr. 12, 1901. Serial No. 58,694. (No model.)

Claim.—In a shade-roller bracket, the combination with the supporting-plate having an offset end and formed with a longitudinal slot

and with a vertical slot or opening at the outer end of the longitudinal slot and at the junction of the offset end, one wall of said slot being provided with a row of rack-teeth, of an angular bracket, the apex of which is formed with notches and one arm of which is provided with a rack and with a T-shaped head, said rack being of less width than the width of the longitudinal slot whereby the bracket-arm is permitted to tilt axially and engage the rack-teeth aforesaid to lock the bracket-arm in longitudinal adjustment, substantially as set forth.

696,569. DEVICE FOR GENERATING GAS FOR USE IN EX-PLORATION-ENGINE. JONAS S. KILLIAN, Klamath, Cal. Filed Nov. 28, 1900. Serial No. 24,006. (No model.)

Claim.—1. In a vaporizer for use in explosion-engines, the combination of the drum A forming the casing and gas-generating chamber; the shield B above the generating-chamber and between the same and the casing A; the exhaust-chamber E in the generating-chamber; ports F to admit the products of explosion into said chamber; port G to discharge said products from said chamber to the open air; a scraper J, adapted to scrape the exterior of the exhaust-chamber, and having means for its rotation, as shown; oil-supply pipe leading into the generating-chamber; and gas-supply pipe leading to the explosion-chamber of the engine; the reflux-chamber F, below the generating-chamber, having removable bottom, as shown; drip-pipe H leading from the reflux-chamber; and the swinging valve stopper U, mounted intermediate the generating and the reflux chambers.

2. In a hydrocarbon-vaporizer for explosion-engines, a gas-generating chamber having connection with a hydrocarbon-supply and also with the explosion-chamber of the engine; an exhaust-chamber in the gas-generating chamber, connected with the discharge-port of the engine, and having a port leading therefrom to the outer air; the casing of said chamber being cylindrical on its exterior; oil-supply pipes arranged to discharge the oil into the generating-chamber and onto the top of the exhaust-chamber; a swinging scraper, with a crank affixed thereto to operate the same; the said scraper arranged to scrape the exterior of the exhaust-chamber as the crank is rotated.

3. A cylindrical casing A, forming a gas-generating chamber; a cylindrical casing in said chamber, forming an exhaust-chamber E arranged concentrically therein; oil-supply pipes leading into the gas-generating chamber and located to discharge the oil above and onto the casing of the exhaust-chamber and a gas-pipe H leading from the generating-chamber to the cylinder of engine; and means to scrape said casing, as shown.

4. In a carburetor provided with a gas-generating chamber, and an exhaust-chamber; the generating-chamber; a reflux-chamber below the generating-chamber, and having valvular connection therewith; a valve-stopper U, adapted to open and close the connection between the chambers; and means to operate said stopper, substantially as shown.

696,570. PIN. HARRMAN A. KIRKALL, New York, N. Y. Filed June 26, 1901. Serial No. 58,129. (No model.)

Claim.—The herein-described pin having a hardened or tempered head and point, and a relatively soft and pliable body or shank portion between the head and point.

696,571. STOPPER FOR BOTTLES. GEORGE KORN, New York, N. Y., assignor to Harry G. Korn, New York, N. Y. Filed July 9, 1900. Serial No. 608,618. (No model.)

Claim.—1. The bottle or receptacle having the thickened section C of unyielding material surrounding its throat-passage and being exterior to said passage so as to leave the latter substantially unobstructed, said section having the vertically-disposed annular groove opening upwardly in its upper edge and disposed outwardly beyond the side walls of said throat-passage, combined with the stopper or cap initially having the two-part annular depending flange adapted to enter and firmly bind against the walls of said groove, the initial diameter of said flange being greater than the diameter of said groove, whereby said flange upon being driven into said groove and between the unyielding walls thereof becomes contracted and conformed to said walls and enters into sealing contact therewith; substantially as set forth.

2. In combination with the receptacle having the annular vertical upwardly-opened groove enclosing its mouth, the stopper or cap having the annular depending flange to enter and tightly fit said groove and also having the depending plug portion to enter and tightly fit the walls of said groove; substantially as set forth.

3. In combination with the receptacle having the annular vertical upwardly-opened groove enclosing its mouth, the stopper or cap having the annular depending flange to enter and tightly fit said groove and also having the depending plug portion whose lower end is dished and capable of being flattened, to enter and tightly fit said mouth, said stopper or cap being of ductile material; substantially as set forth.

4. The bottle or receptacle having the thickened section D of unyielding material surrounding its throat-passage and being exterior to said passage so as to leave the latter substantially unobstructed, said section having the vertically-disposed annular groove opening upwardly in its upper edge and disposed outwardly beyond the side walls of said throat-passage, combined with the stopper or cap initially having the upwardly-opened trough-like two-part annular depending flange adapted to enter and firmly bind against the walls of said groove, the initial diameter of said flange being greater than the diameter of said groove, whereby said flange upon being driven into said groove and between the unyielding walls thereof becomes contracted and conformed to said walls and enters into sealing contact therewith; substantially as set forth.

696,572. TIME-RECORDER. CAROL J. C. KROHN and CHRISTIAN A. KROHN, Christiansburg, Norway. Filed Aug. 26, 1900. Serial No. 38,851. (No model.)

Claim.—1. The combination with a chute for the reception of a record-clip and means automatically positioning type adjacent to an opening in said chute; of a platen, hand-actuated appliance moving said platen from a normal position to the type across the chute, means automatically moving said platen back to normal position, a gate normally closing the delivery end of the chute and adapted to hold a record-clip in the path of the platen, a locking device for said gate, means on the platen acting on the locking device to release the gate and thereby open the chute, when a record-clip is being printed on, and means, operated by the platen when moving back to normal position, and operating to move the gate and lock it into its normal position, substantially as and for the purpose set forth.

2. The combination with a chute for the reception of a record-clip, and means automatically positioning type adjacent to an opening in said chute; of a platen, hand-actuated appliance moving said platen from a normal position to the type, means automatically moving the platen back to normal position, a gate normally closing the delivery end of the chute and adapted to hold a record-clip in the path of the platen, a resilient support for said gate, means on the platen moving said support out of engagement with the platen when a record-clip is being printed on and thereby opening the delivery end of the chute, and means, operated by said platen when moving back to normal position, to move the gate back into engagement with its support and thereby again close the delivery end of the chute, substantially as and for the purpose set forth.

3. The combination with a chute for the reception of a record-clip, and means automatically positioning type adjacent to an opening in said chute; of a platen, hand-actuated appliance moving said platen from a normal position to the type, means automatically moving the platen back to normal position, a gravity-gate normally closing the delivery end of the chute and adapted to hold a record-clip in the path of the platen, a locking device for said gate, means on the platen acting on the locking device to release the gate and thereby cause it to swing out of the chute, when a record-clip is being printed on, and a spring connection between the gate and platen operating to move said gate back into the chute and into engagement with the locking device when said platen is moving back to normal position, substantially as and for the purpose set forth.

4. The combination with a chute for the reception of a record-clip and means automatically positioning type adjacent to an opening in said chute; of a polygonal or block-like platen slidable in ways, hand-actuated appliance moving said platen from a normal position to the type, means automatically moving the platen back to normal position, a gravity-gate normally closing the delivery end of the chute and adapted to hold a record-clip in the path of the platen, a locking device for said gate, means on the platen acting on the locking device to release the gate and thereby cause it to swing out of the chute, when a record-clip is being printed on, and a spring connection between the gate and platen operating to move said gate back into the chute and into engagement with the locking device when said platen is moving back to normal position, substantially as and for the purpose set forth.

5. The combination with the type-wheels 19 and 20, the toothed wheels 16 and 17 respectively secured to wheels 19 and 20, the toothed wheels 5 and 6 and the spring-controlled levers 7 and 8, each carrying a spring-actuated pawl 12 engaging wheels 16 and 17 respectively; of an open-ended chute into a slot of which the above-described type-wheel project, a platen having motion to and from said type-wheel across the chute, and a gate for the latter under the control of the platen and operating to close and open the passage through the chute below the type-wheel, for the purpose set forth.

6. The combination with the type-wheels 19 and 20, the chute 55 into an aperture of which said wheels project, said chute having its opposite apartured wall extended below said type-wheels and the spring 63 having offset 64 and lateral projection 65 secured to said extended wall and projecting into the aperture thereof, the platen 23 having block 66 on its under side provided with lateral projections x, y, and means for moving said platen to and from the type-wheels; of the swinging gate 29 connected by spring with the rear end of the platen and having on its hub a radial arm 67 provided with a lateral projection 68, said parts constructed and operating substantially as and for the purpose set forth.

696,578. PIN-TICKET. JOHN P. KROHN, Dayton, Ohio, assignor to the National Tag Co., Dayton, Ohio, a Corporation of Ohio. Filed Oct. 19, 1901. Serial No. 78,228. (No model.)

Claim.—The herein-described pin-ticket, comprising a blank having two folds, one of which provides two leaves, and the other of which provides an including leaf for the head of the pin, a pin united to said ticket by means of said including leaf, and the opposite end of said ticket having two circular slots which provide openings for the penetration of the pin in making the leaves of the ticket, the said circular slots being concentrically disposed and the adjacent ends thereof terminating a suitable distance from each other to provide an intervening portion between the ends of said slots and through which portion the ticket is bent to increase the openings therein provided by said slots, substantially as and for the purpose specified.

696,574. STORM-APRON FASTENER. CHARLES C. LARSEN, Grinnell, Iowa. Filed July 29, 1901. Serial No. 66,908. (No model.)

Claim.—In a fastener of the character described, a U-shaped member, a loop-shaped member having eyes intermediate the ends of its side bars, a cross-bar loosely supported in the said eyes so as not to interfere with the lateral movement of the side bars, and cooperating eyes and journals at the extremities of the side bars of the said members for positively pivotaly connecting them, the said side bars being laterally movable to admit of the coupling and the uncoupling of the aforesaid members, substantially as specified.

696,575. MACHINE FOR MIXING AND KNEADING DOUGH OR ANALOGOUS MATERIALS. JAMES LEE, Boston, Mass., assignor, by mesne assignments, to National Bread Company, New York, N. Y., a Corporation of New Jersey. Filed Sept. 4, 1901. Serial No. 74,827. (No model.)

Claim.—1. A mixing and kneading machine provided with one or more sets of reciprocating pistons operatively connected with a driving-shaft; in combination with two spiral conveyors operatively connected with the same shaft; together with means for changing the direction of rotation of one of the conveyors.

2. A mixing and kneading machine provided with one or more sets of reciprocating pistons operatively connected with a driving-shaft; in combination with two spiral conveyors operatively connected with the same shaft; together with means for changing the direction of rotation of one of the conveyors, and a door located at one end of the machine, whereby the conveyors are adapted to act in the first instance as mixing devices and in the second instance as means for conveying the completed product away from the machine.

3. A mixing and kneading machine provided with one or more sets of reciprocating pistons; together with a pair of rotary mixing devices or conveyors and interconnecting mechanism for both, operatively connected with a source of power; in combination with disconnecting mechanism for the reciprocating pistons and change-gear mechanism for one of the rotary mixing devices or conveyors, the arrangement being such that the pistons may be disconnected from the source of power and the direction of rotation of one of the mixing devices be reversed so as to cause the material to be moved toward one end of the machine.

4. A mixing and kneading machine provided with a removable door located in the bottom of the mixing and kneading trough; together with operating means so arranged that the door may be first lowered and then moved laterally beneath the bottom of the mixing and kneading trough.

5. A mixing and kneading machine provided with a removable door located in the bottom of the mixing and kneading trough and having mechanism for locking it in its upper or closed position; together with means for first lowering it and then moving it laterally to its complete open position.

6. A mixing and kneading machine consisting of a series of reciprocating pistons, a pair of rotary mixing devices or conveyors all operatively connected to a source of power and located within a mixing and kneading trough; together with a removable door located in the bottom of the trough and provided with means for first lowering it and then moving it laterally to its complete open position.

7. A mixing and kneading machine consisting of a series of reciprocating pistons and a pair of rotary spiral mixing devices or conveyors, all operatively connected to a source of power, and provided with means for disconnecting the reciprocating pistons from the source of power; and additional means for reversing the direction of movement of one of the conveyors; together with a removable door located beneath the bottom and at one end of the mixing and kneading trough and between the conveyors, said door being provided with means for lowering it and then moving it laterally to its complete open position, all of said parts acting substantially as and for the purpose described.

696,576. GOLD-DREDGE. THOMAS E. LEE, Farmington, N. Mex. Filed Aug. 19, 1901. Serial No. 73,509. (No model.)

Claim.—1. A dredge consisting of a tapering tubular body part-circular in length and provided with an air-hole in one end and with a bit or blade at its opposite end; in combination with cables to move it forwardly, rearwardly and vertically to rotate it on its axis, substantially in the manner specified.

2. A dredge, consisting of a tapering tubular body, part-circular in length and provided with an air-hole in one end, and with a bit or blade at its opposite end, substantially as set forth.

696,577. GRAIN-SCOURER. WHEATLEY LEE, Washell, N. H. Filed Sept. 11, 1901. Serial No. 75,020. (No model.)

Claim.—1. The combination of a horizontal scouring-case, a stationary partition arranged therein and having a concave face and a central discharge-opening, and a rotary scouring and propelling device which projects into the concave face of the partition and which is composed of an annular series of radial, inclined wings which face with their rear edges the concave face of the partition and which are separated by deep passages extending between the wings from the front edges to the rear edges thereof, substantially as set forth.

2. The combination of a scouring-case, of a stationary partition arranged therein and having a central discharge-opening and a concave face, a rotary scouring and propelling device projecting into the concave face of said partition and provided with an annular series of radial inclined wings having the edges facing the partition of substantially the same curvature as the concave face of the case, substantially as set forth.

3. The combination with a scouring-case, of successive pairs of stationary partitions and rotating rotary scouring and propelling devices, said stationary partitions having concave faces and central discharge-openings, and said rotary scouring and propelling devices having inclined wings, and a propeller arranged between each partition and the next-following rotary scouring and propelling device, substantially as described.

696,578. LOCK-STITCH SEWING-MACHINE. MICHAEL MARK, New York, N. Y., and ARTHUR GUERRA, Philadelphia, Pa. Filed Oct. 15, 1901. Serial No. 73,794. (No model.)

Claim.—1. In an outside lock-stitch machine, the combination of a speed-holder with a hooked needle, a thread-thrower, a thread-carrier, a take-up lever, and with a pair of slides, to both of which the thread-carrier is connected, substantially as specified.

2. In an outside lock-stitch machine, the combination of a speed-holder with a wax-pot, means for conducting the speed-thread from the speed-holder first into and then out of the wax-pot, means for looping a needle-thread, and means for passing the looped needle-thread around the speed-holder and wax-pot, substantially as specified.

696,579. TRACK-WRENCH. JOHN W. HOSKINS, Salt Lake City, Utah. Filed Apr. 17, 1901. Serial No. 64,314. (No model.)

Claim.—1. In a track-wrench, a frame, a yieldable socket carried by the frame, means for clamping the frame to the rail, sprocket-gearing for operating the socket, and a cushioning-spring to permit the vertical adjustment of the wrench toward and from the track-rail, substantially as described.

2. In a track-wrench, a frame, a yieldable, rotatable socket carried by said frame, a rock-shaft provided with clamping-arms mounted in the frame, a cushioning-spring adapted to engage the top of the rail, and provided with a slot, a driving-sprocket connected with the driven sprocket on the socket-shaft, combined with means for moving the machine longitudinally upon the rail.

3. In a track-wrench, a frame, a yielding socket-shaft journaled in the frame, an arm rigidly connected to the frame, a spring on the arm, a lever fulcrumed on the frame, one end of said lever engaging the spring on the right arm and the other end adjustably secured to the socket-shaft whereby the said socket-shaft is held in constant engagement with the nut to be turned.

4. In a track-wrench, a frame, a rotatable socket yieldably mounted

upon the frame, a spring-pressed lever pivoted to the frame and connected with the socket to hold the same in constant engagement with the nut to be turned, means for clamping the frame to the rail combined with means independent of the clamping means for moving the frame along the rail.

5. In a track-wrench, the combination with a frame, of gripping-jaws secured thereto by a link connection and adapted to be swung lengthwise of the rail, plates on the jaws to engage the sides of the rail, rods connecting the plates and extending across the rails to limit the downward throw of the jaws, means to normally hold the gripping-jaws expanded and a spring to maintain the jaws in a vertical position.

6. In a device of the class described, a frame adapted to rest upon the rail, a yieldable socket carried by said frame, a cushioning-spring secured to the frame and provided with a longitudinal slot, clamping-arms adapted to engage the sides of the rail, sprocket-gearing for operating the socket, combined with means for moving the machine along the rail, said means consisting of gripping-jaws having the plates to engage the sides of the rail, said jaws adapted to be attached to the frame by a universal joint, and a spring to maintain the jaws in a vertical position, substantially as described.

7. In a track-wrench, the combination with the frame of a cushioning device to permit the vertical adjustment of the wrench toward and from the track-rail.

696,580. SAND-DRIVER. JAMES A. HOSKINS, Salt Lake City, Utah. Filed Apr. 18, 1901. Serial No. 64,128. (No model.)

Claim.—1. A sand-driver embodying the following construction, to wit, a vertical stack, a furnace located near the base of the stack and having a fine leading into the stack near the upper end, a discharge-flue leading from the stack near the bottom, whereby the products of combustion pass to the top of the stack and thence down through the stack to the exit-opening, a shoveling mechanism for feeding sand into the stack above the furnace-flue, and baffle-plates located above the discharge-flue and a sufficient distance below the furnace-flue opening to permit the sand to travel in the direction of said with the downwardly-moving gases before striking the baffle-plates, whereby the sand is dried sufficiently to prevent stoppage of the spaces between the plates, substantially as described.

2. A sand-driver embodying the following characteristics, to wit, a mechanism for shoveling sand, a vertical stack having a straight passage down through which said sand is shovelled in a free state, a furnace opening into the upper part of said passage, an exit-opening from the lower part of the stack whereby the heated products are caused to travel in the same direction and with the sand while descending freely in the stack and baffle-plates for arresting the direct fall of the sand; substantially as described.

696,581. SELF-LOADING BUCKET FOR DREDGING. JAMES A. HOSKINS, Salt Lake City, Utah. Filed Aug. 27, 1901. Serial No. 78,408. (No model.)

Claim.—1. In an apparatus such as described, the combination with the bucket-sections pivotally connected together at proximate sides and links pivotally connected together and to the outer sides of the sections, of a winch journaled in proximity to the pivot of the bucket-sections, a second winch journaled in proximity to the link-pivot, each of said winches having a drum of large and a drum of small diameter, a flexible connection winding from the smaller drum of the lower winch to the larger drum of the upper winch, a flexible connection extending from the smaller drum of the upper winch to the proximate side of the

bucket-section, and an operating flexible connection extending from the large drum of the lower winch; substantially as described.

2. In a self-loading bucket, the combination with the bucket-sections pivotally connected together, and the links pivoted to the outer sides of the sections and pivotally connected together, of means for drawing the pivot between the sections and the pivot between the links toward each other to close the sections, embodying two winches one moving with each pivot and each having a large and small drum, an operating connection with the larger drum of one winch for rotating it, a connection between the smaller drum of that winch and the larger drum of the other winch and a flexible connection winding on the smaller drum of the latter winch for drawing said pivotal points toward each other; substantially as described.

3. The combination with a clam-shell bucket, of means for closing the sections of the bucket embodying two winches each having drums of relatively large and small diameter, a flexible connection with the smaller drum of one winch for closing said sections, a flexible connection between the larger drum of that winch and the smaller drum of the other winch and a flexible operating connection with the larger drum of the latter winch; substantially as described.

4. The combination with the bucket-sections pivotally connected together, links pivotally connected together and to the respective bucket-sections, and a suspension-cable connected with said links, of winches journaled on the pivot-pins of the bucket-sections and pivot-pins connecting the links respectively, each of said winches having drums of relatively large and small diameter, a flexible connection extending from the smaller drum of the upper winch to the pivot-pin of the bucket-sections, a flexible connection extending from the larger drum of said winch to the smaller drum of the lower winch, a flexible operating connection connected with the larger drum of the latter winch and a guide-pulley for said flexible connection; substantially as described.

696,582. METALLIC TIN AND RAIL-FASTENER. EMMA E. MYERS, Pittsburgh, Pa. Filed Nov. 30, 1901. Serial No. 64,161. (No model.)

Claim.—In a railway-chair, the combination with the rail seated therein, an eccentric, a bolt secured on said chair, a screw-threaded bolt, and a nut rigidly secured to the upper end of said bolt and a nut removably secured to the lower end of said bolt, all parts being arranged and operating substantially as described.

696,583. RAILROAD-RAIL. EMMA E. MYERS, Pittsburgh, Pa. Filed Nov. 30, 1901. Serial No. 64,162. (No model.)

Claim.—A rail having an opening, slot and recess formed therein on its one end and beveled on its other end and having an opening formed therein, a hook member, a second rail carrying a head, neck and flange on one end and beveled on the opposite end, said rail having formed therein an opening and carrying a hook member, all parts being arranged substantially as described, and for the purpose set forth.

696,584. MANIPULATING ACCOUNT DEVICE. ORIAS GRUBBS, Louisville, Ky. Filed Mar. 13, 1901. Serial No. 61,891. (No model.)

Claim.—1. The combination in an accounting device, of a rigid file-base having two sets of posts set in lines at right angles to each other, a merchant's file-book detachably retained on one of said sets of posts, a removable customer's book with perforations fitting over the other of the sets of posts so as to interlock with the other book, and a card carrying a sheet of carbon-paper attached at one side and held to loosely slide on the latter posts, the carbon-paper interlocking with the books so that the writing on the merchant's file-book may be copied in facsimile in the removable customer's book.

2. The combination of a set of customer's post-books perforated at one end, with a set of files carrying each a merchant's book removably fastened on a set of posts, said file having a set of posts in a line at right angles to the first set to support the customer's book and loosely carrying a card having a carbon-sheet attached at one side thereof, for the purpose set forth.

3. The combination of a post-book perforated at one end, a file carrying a book removably held on posts at one side thereof, and having at each end a pair of slotted posts either pair of which may hold the post-book loosely in place and a card loosely fastened to slide on one pair of said end posts, held thereon by a pin and having a carbon-sheet interlocking with the leaves of the said books.

4. An account-tablet comprising a base having at each end a pair of slotted posts and at one side a pair of posts split and notched inside, a book perforated at the side to register with said posts, means for holding said book in place, and a card carrying a sheet of carbon-paper and having holes registering with either of the two sets of end posts and held loosely thereon by a pin playing freely in the slots thereof.

5. In an accounting device a file comprising a base having a set of end posts split to allow free play of a pin therein, a second set placed in line at right angles to the first set and slotted and notched on the inside to hold a card therein at different elevations, in combination with a card carrying a sheet of carbon-paper and perforated and fitting on the said end posts of the file-base and held loosely thereon by a pin, as described.

696,585. VEHICLE-TIRE. WILLIAM H. GUERREAU, Poughkeepsie, N. Y., assignor of one-third to WILLIAM TYLER SMITH, Poughkeepsie, N. Y. Filed Oct. 7, 1901. Serial No. 77,807. (No model.)

Claim.—1. A vehicle-tire comprising an elastic tube having a plu-

rality of pockets, and an insulating body in each pocket, each of said bodies having a diameter sufficiently less than that of its pocket to permit of partial collapse of the pocket and subsequent compression of the body between the opposite walls thereof.

2. A vehicle-tire comprising an elastic tube having a plurality of pockets, and an insulating body disposed loosely in each pocket, each of said bodies having a diameter sufficiently less than that of its pocket to permit of partial collapse of the pocket and subsequent compression of the body between the walls of the pocket.

3. A vehicle-tire comprising an elastic tube having spherical pockets therein, and an insulating body disposed loosely within each pocket, each of said bodies having a diameter sufficiently less than that of its pocket to permit of partial collapse of the pocket and subsequent compression of the body between the walls of the pocket.

4. A vehicle-tire comprising an elastic tube having a plurality of insulating bodies therein, each body having a diameter sufficiently less than that portion of the tire in which it is disposed, to permit of partial collapse of the tire and subsequent compression of the body between the walls of the tire.

5. A vehicle-tire comprising a body portion of elastic material having spherical pockets therein and intercommunicating passages, and an insulating ball in each pocket, said balls having each a diameter sufficiently less than that of its pocket, to permit of partial collapse of the pocket and subsequent compression of the ball between the walls of the pocket.

6. A vehicle-tire comprising a body portion of elastic material having spherical pockets therein and intercommunicating passages, the area of the passages and the centers of the pockets lying in the same circle, and an insulating ball disposed loosely within each pocket, the diameter of each ball being sufficiently less than that of its pocket to permit of partial collapse of the pocket and subsequent compression of the ball between the walls of the pocket.

696,588. BOLT-ANCHOR. FRANKLIN E. PALMER, Brooklyn, N. Y. Filed July 9, 1901. Serial No. 67,619. (No model.)

Claim.—1. A bolt-anchor having a tapering bore placed at an angle to the longitudinal axis of the anchor.

2. A bolt-anchor having a tapering threaded bore placed at an angle to the longitudinal axis of the anchor.

3. A bolt-anchor having a tapering threaded bore placed at an angle to the longitudinal axis of the anchor, but having the center of the smaller end of said bore coincident with said axis.

4. A bolt-anchor formed of a plurality of pieces and provided with a tapering threaded bore placed at an angle to the longitudinal axis of the anchor.

5. A bolt-anchor formed of a plurality of pieces and provided with a tapering threaded bore placed at an angle to the longitudinal axis of the anchor but having the center of the smaller end of said bore coincident with said axis.

6. A bolt-anchor having a smooth external surface and provided with a tapering threaded bore placed at an angle to the longitudinal axis of the anchor.

7. A bolt-anchor having a smooth external surface and provided with a tapering threaded bore placed at an angle to the longitudinal axis of the anchor but having the center of the smaller end of said bore coincident with said axis.

8. A bolt-anchor having a tapering threaded bore placed at an an-

gle to the longitudinal axis of the anchor and provided with an external retaining-ring.

9. A bolt-anchor having a tapering threaded bore placed at an angle to the longitudinal axis of the anchor and provided with an external retaining-ring fitting into a groove provided therefor.

10. A bolt-anchor formed of a plurality of pieces and provided with a tapering threaded bore placed at an angle to the longitudinal axis of the anchor and provided with means for registering the pieces.

698,587. BOLT-ANCHOR. FRANKLIN E. PALMER, Brooklyn, N. Y. Filed Jan. 21, 1902. Renewed Jan. 22, 1902. Serial No. 99,992. (No model.)

Claim.—1. A bolt-anchor consisting of a sleeve of soft metal provided with inner longitudinal ribs, substantially as described.

2. A bolt-anchor consisting of a soft-metal sleeve provided with a bore tapering from end to end and with inner longitudinal ribs, substantially as described.

3. A bolt-anchor consisting of a soft-metal sleeve and provided with outer and inner longitudinal ribs, substantially as described.

4. A bolt-anchor consisting of a soft-metal sleeve having a tapering bore and provided with inner and outer longitudinal ribs, substantially as described.

5. A bolt-anchor consisting of a soft-metal sleeve slotted longitudinally from one end throughout nearly its whole length and provided with inner longitudinal ribs, substantially as described.

698,589. MACHINE FOR TREATING HIDES OR SKINS. FRANKLIN E. PALMER, Woburn, Mass., assignor to Vaughan Machine Company, Boston, Mass., a Corporation of West Virginia. Filed Oct. 2, 1901. Serial No. 77,992. (No model.)

Claim.—1. In a machine for treating hides and skins, the combination with a bed-roll, a feed-roll and a movable support therefor, of a roll cooperating with both the said bed-roll and feed-roll and bodily movable with relation thereto, means to effect movement of said support in one direction, and means to effect movement of the bodily-movable roll toward and away from said bed-roll and feed-roll, substantially as described.

2. In a machine for treating hides and skins, the combination with a bed-roll, a feed-roll and a sliding support therefor, of a plash-roll co-operating with both the said feed-roll and said bed-roll, a shaft, and mechanism operated by said shaft to move said sliding support in one direction and to move said plash-roll bodily with relation to the said roll and feed-roll, in another direction, substantially as described.

3. In a machine for treating hides and skins, a rotatable half-cylinder, a carriage movable toward and from the same, a bed-roll carried

by said carriage and co-operating with said half-cylinder, a roll co-operating with said bed-roll and bodily movable toward and from the same, means for said bodily-movable roll attached to said carriage, means to reciprocate said carriage, and means to move said bodily-movable roll, substantially as described.

4. In a machine for treating hides and skins, a rotatable cylindrical tool, a carriage movable toward and from said tool and composed of two parts, one of which is movable on the other, a bed-roll, a feed-roll, and a plash-roll carried by said carriage, a yielding medium to normally hold the two parts of the carriage so as to move as one body and which permits the part carrying the said rolls to move independent of the other part of said carriage, means to reciprocate said carriage, and means to move the plash-roll bodily with relation to said bed-roll and feed-roll, substantially as described.

5. In a machine for treating hides and skins, the combination with a rotatable roll, a reciprocating support therefor, a cam-shaft, mechanism connecting said support with said cam-shaft to effect the reciprocation of the said support, a main or driving shaft, mechanism for connecting said roll with said main shaft, a cam on said cam-shaft controlling the rotation of the said roll, means for driving the cam-shaft from the said main shaft, and mechanism under control of the operator for controlling said means, substantially as described.

6. In a machine for treating hides and skins, a cam-shaft, a driving-shaft, mechanism under the control of the operator for connecting said cam-shaft with said driving-shaft, a cam on said cam-shaft, a roll to engage the hide or skin, and mechanism connected with said roll and controlled by said cam to alternately engage the said roll with and disengage it from said hide or skin, substantially as described.

7. In a machine for treating hides and skins, the combination with a support for the hide or skin, of a roll to engage the hide or skin bodily movable toward and from said support a rotatable shaft, mechanism connecting said roll with said shaft for producing bodily movement of said roll by the rotation of said shaft, and means independent of said mechanism to guide said roll in its bodily movement, substantially as described.

8. In a machine for treating hides and skins, the combination with a tool to operate on the hide or skin, of a bed-roll co-operating therewith, a reciprocating carriage for said bed-roll, a rotatable shaft, and mechanism connecting said carriage with said shaft to produce reciprocation of said carriage by the rotation of said shaft, substantially as described.

9. In a machine for treating hides and skins, a roll to engage the hide or skin, a cam-shaft, a driving-shaft, mechanism connecting said cam-shaft with said driving-shaft, a cam on said cam-shaft, and independent mechanism for rotating said roll under the control of said cam, substantially as described.

10. In a machine for treating hides and skins, a bodily-movable roll to engage the hide or skin, a shaft, mechanism connecting said roll with said shaft whereby rotation of said shaft produces bodily movement of said roll, a power-shaft, mechanism connecting said power-shaft with the shaft to which said roll is connected, and means for automatically effecting intermittent rotation of the said roll-operating shaft and bodily movement of said roll, substantially as described.

11. In a machine for treating hides and skins, a rotatable roll to engage the hide or skin, a clutch mechanism governing the rotation of said roll, a cam-shaft, a cam thereon governing the action of said clutch mechanism, a second clutch mechanism governing the rotation of said cam-shaft, and means to control the action of said second clutch mechanism, substantially as described.

12. In a machine for treating hides and skins, a rotatable roll to engage the hide or skin, a power-shaft, a clutch mechanism on said power-shaft governing the rotation of said roll, a cam-shaft, a cam thereon governing the action of said clutch mechanism, a second clutch mechanism governing the rotation of said cam-shaft, and means to control the action of said second clutch mechanism, and means to lock the cam-shaft from rotating and maintain the first-mentioned clutch mechanism under the control of the cam, substantially as described.

13. In a machine for treating hides and skins, the combination with a reciprocating carriage, a support for the hide or skin movable therewith, a roll to engage the hide or skin movable with said carriage and toward and from the same, mechanism to reciprocate said carriage, and means to move the said roll toward and from said carriage, substantially as described.

14. In a machine for treating hides and skins, the combination with a movable support, a roll to engage the hide or skin movable with said support and toward and from the same, mechanism to move said support, and means to move the said roll toward and from said support, substantially as described.

698,589. BRIDGE-GATE. FRANK I. PALMER, Sturgeon Bay, Wis. Filed Sept. 28, 1901. Serial No. 77,116. (No model.)

Claim.—1. The combination with a partly-counterbalanced gate, of a catch for normally holding the same in an elevated position, and

mechanism adapted to be operated by the opening of the draw to move said catch to releasing position.

2. The combination with a gate and means for elevating the same, of a catch for holding said gate normally in elevated position, operating-fingers carried by the draw and mechanism for connecting said fingers to the holding-catch to effect the release of the gate upon the movement of the draw in either direction and permit the gate to descend by gravity to the surface of the bridge.

3. The combination with a gate and means for holding the same in an elevated position, of a bell-crank lever having one arm oppositely connected to said holding means, and operating-fingers carried by the draw and adapted to engage the opposite arm of said bell-crank lever.

4. The combination with a gate, of a shaft, a sprocket-wheel thereon, a link belt connected to said sprocket-wheel and having its upper end connected to the gate, counterbalance-weight arranged at the lower end of said link belt, a pinion, ratchet mechanism connecting the same to the shaft, and means adapted to be operated by the draw for engagement with said pinion.

5. The combination with the gate, of a shaft, a sprocket-gear thereon, a link belt passing over said sprocket-wheel and connected at one end to the gate, a pinion, ratchet mechanism connecting the same to the shaft, oppositely-disposed loose rack-bars for engagement with said pinion, mechanism carried by the draw for engaging with and moving said rack-bars, and means for effecting the disengagement of such mechanism, substantially as specified.

6. The combination with the gate, of a shaft, a sprocket-gear thereon, a link belt passing over said sprocket-wheel and connected at one end to the gate, a pinion, ratchet mechanism connecting the same to the shaft, loose rack-bars for engagement with said pinion, pivoted levers carried by said rack-bars and pins carried by the draw for engagement with said levers, substantially as specified.

7. The combination of the gate, a shaft, a sprocket gear thereon, a link belt passing over said sprocket-wheel, cords or chains connecting the upper end of the link belt to the opposite ends of the gate, a counterbalance-weight connected to the lower end of said link belt, a pinion, ratchet mechanism connecting the same to the shaft, loose racks arranged on each side of and adapted to engage said pinion, means for supporting and guiding said racks a counterbalance-weight connected to each rack for returning the same to initial position, a hook carried by each rack, pins projecting from the draw for engagement with said hooks, and means for effecting the disengagement of said pins and hooks, substantially as specified.

8. The combination of the gate 7, means for guiding the same, a link belt 12, cords or chains 10 connecting said link belt to the opposite ends of the gate, a sprocket-wheel 14 for driving said link belt, a counterbalance-weight 15 carried at the lower end of the link belt, a shaft 22 on which said sprocket-wheel is mounted, a pinion 23, a ratchet mechanism 24 connecting the same to said shaft, a fixed frame 25, loose racks 26 guided in said frame and adapted to engage the pinion, counterbalance-weights 28 for said racks, levers 29 carried by said racks, pins 30 carried by the draw for engagement with said hooks, antifriction-rollers 32 for

effecting the disengaging of the hook from the pin, a spring-catch 18 normally acting to maintain the gate in an elevated position, a bell-crank lever 19 having one arm connecting to said catch, the finger 21 carried by the draw and adapted to engage with the opposite arm of said bell-crank lever, substantially as specified.

696,590. PACKING FOR STUFFING-BOXES. JOHANN C. A. FLINT, Hamburg, Germany. Filed June 20, 1901. Serial No. 65,268. (No model.)

Claim.—A packing composed of a series of superposed semi-circular wedge-shaped rings arranged in pairs, both faces of each ring being formed by straight planes of which one extends at right angle to the plane-axis, while the other is inclined to said axis, substantially as specified.

696,591. HYDROCARBON-BURNER. CHARLES W. FOWLE, San Jose, Cal. Filed June 18, 1901. Serial No. 64,967. (No model.)

Claim.—1. A hydrocarbon-burner, including a spherical casing having a discharge, an oil-feed pipe entering the casing and coiled therein, and a coiled steam-pipe within the casing having its ends substantially following the coils of the oil-feed pipe whereby said pipes lie contiguous to each other and the heat of the steam will be imparted to the oil to raise the temperature of the oil approximately to that of the steam, said oil-pipe having its mouth adjacent to the discharge end of the steam.

2. In a hydrocarbon-burner the oil and steam pipes, both coiled and

with the coils of one substantially following and adjacent to the coils of the other, one of said pipes having its discharge end adjacent to the discharge end of the other pipe, and a closed spherical casing having a chamber which incloses both of said pipes and forms a receiver for heated vapor whereby the vapor in the chamber assists in heating the oil-pipe and forms a cushion substantially as and for the purpose described.

3. In a hydrocarbon-burner a spherical casing having radially-disposed steam-inlet, oil-inlet and discharge, said casing having an opening in one side, and a removable closure for said opening; steam and oil pipes coiled substantially concentrically within the chamber, one of said pipes having its discharge end proximate to and in line with the discharge of the other pipe, said pipes discharging into the chamber and said chamber serving as a superheater for the oil delivered to the same.

696,592. HAND-FASTENER. GEORGE F. RAKE, Des Moines, Iowa. Filed June 18, 1901. Serial No. 65,957. (No model.)

Claim.—1. In a hand-fastener, a lug having a slot for the reception of the end of the band, an opening for the reception of a bolt, runways one on either side of said opening, and a roller mounted in each runway, substantially as described.

2. In a hand-fastener, a lug having a slot for the reception of the end of the band, a centrally-arranged opening for the reception of a bolt, runways one on each side of said opening, a toe controlling each runway, and a roller mounted in each runway, substantially as described.

3. In a hand-fastener, a lug having a slot for the reception of the end of the band, a longitudinal central opening for the reception of a bolt, inclined runways one on each side of said opening, and a roller mounted in each runway, substantially as described.

4. In a hand-fastener, a lug having a longitudinal slot for the reception of the end of the band, a wall above the slot having an inclined face, an inclined top portion, the wall and top portion forming runways one on each side of the central opening for the bolt, a roller mounted in each runway, and means for retaining the roller in position, substantially as described.

696,593. STUMP-EXTRACTOR. CHARLES E. REIDMAN, Abertysia, Tex. Filed Oct. 16, 1901. Serial No. 73,576. (No model.)

Claim.—In a machine of the class described, the portable truck, a horizontally-slotted casing carried by the truck and provided with a cable-opening at one end, said casing also having in the upper and lower sides thereof separate parallel rows of pin-receiving holes, the holes of the opposite rows being transversely inclined, main and auxiliary cables being slidably associated with the opposite rows of the holes, a horizontally-arranged power-lever having its head and working in the slot of the casing and provided with spaced notches corresponding, respectively, with the separate pins, a clevis fitted to the lever between its notches, a main-cable extending through the end opening of the casing and connected with the said clevis, and an anchor connection at the end of the casing opposite the said cable-opening.

696,594. LUBRICATING-PULLY. WILLIAM RAY, London, England. Filed Nov. 4, 1901. Serial No. 61,591. (No model.)

Claim.—1. A lubricating pulley or wheel, provided within and around its bore with a series of cam-ridges and a series of short channels in its intermediate solid portions connecting said cam-ridges, and a bushing fitting the solid portion of the bore and forming one wall of the reservoir formed by the said cam-ridges and short channels, the said bush having in its inner wall a helical groove and a channel connecting said groove with one of the said short channels; substantially as described.

2. A lubricating pulley or wheel provided within and around its bore with an eccentrically-arranged series of cam-ridges, a series of short channels *j* in its intermediate solid portions *i*, and a filling-opening, and a bushing *e* fitting the bore and forming one wall of the reservoir *c* formed by said cam-ridges; the said bushing having a series of helical grooves *f* in its inner wall and channels *k* leading from the said grooves to the channels *j*, and an absorbent material in the grooves *f*; substantially as described.

696,595. PAPER-MAKING MACHINE. JAMES H. RYDBLUM, Minneapolis, Minn., assignor to George J. O'Donerty and Walter Van derburg, Boston, Mass. Filed Jan. 17, 1901. Serial No. 62,602. (No model.)

Claim.—1. In a paper-making machine, the combination of a suitable frame, a single couch-roll, a Fourdriner wire passing over said roll, and means located immediately adjacent to said roll and beneath the lower reach of the wire, to maintain said wire under requisite tension and cause it to travel with the desired uniformity without the application of pressure upon it at a point where pulp or paper is carried.

2. The combination, in a paper-making machine, of a suitable frame, a Fourdriner wire, and means to maintain said wire taut and cause it to travel without its being engaged by a roll arranged as so to subject the pulp or paper to pressure, said means consisting of a single couch-roll and a tension-roll immediately adjacent thereto and beneath the lower reach of the wire.

3. The combination, in a paper-making machine, of a suitable frame, a single couch-roll, a tension or driving roll immediately adjacent to said couch-roll, and a Fourdriner wire passing between said rolls on its return travel after going over the couch-roll, and means to adjust said tension or driving roll against said wire and toward said couch-roll.

4. The combination, in a paper-making machine, of a suitable frame, a Fourdriner wire, a couch-roll *h*, and a roll adjustably mounted on inclined members to bear against the roll *h* and support the Fourdriner wire therebetween after the paper has been discharged from the Fourdriner wire, substantially as shown.

5. The combination, in a paper-making machine, of a suitable frame, a Fourdriner wire, a couch-roll, and an automatically-adjustable roll *i* arranged on inclined members to support the Fourdriner wire and maintain it taut, said wire being pressed between said rolls after the paper has been discharged from the wire, substantially as shown.

6. The combination, in a paper-making machine, of a suitable frame, a Fourdriner wire, a couch-roll *h*, and a roll *d* in frame on inclined supports *A*, whereby said roll *d* constantly gravitates against said roll *h* with the wire between, below the couching-point, substantially as shown.

7. The combination, in a paper-making machine, of a suitable frame, a single couch-roll, a tension-roll immediately adjacent to said couch-roll, a Fourdriner wire passing over the couch-roll and between the couch and tension rolls, whereby said wire is maintained taut and tensioned against the couch-roll below the couching-point, a felt belt, a supporting-roll *g* for said belt, and press-rolls *e* and *f* back of the couching-point, substantially as shown.

8. The combination, in a paper-making machine, of a Fourdriner wire, an endless felt belt arranged to receive the pulp or paper after it leaves the wire, a press-roll *f* under said belt, a felt-covered press-roll *e* above said roll *f*, a roll *k* bearing against said roll *e*, and a doctor for said roll *k*, substantially as shown.

9. The combination, in a paper-making machine, of a Fourdriner wire, press-rolls one of which is covered with felt, a roll *k* revolving against the surface of the felt-covered roll, and a doctor bearing against the surface of said roll *k*, substantially as shown.

696,596. MOTOR-VEHICLE. WALTER W. BARNETT, Chicago, Ill. Filed Apr. 25, 1900. Serial No. 714,332. (No model.)

Claim.—1. The combination, with a shaft 13, of a tube 17 surrounding the same, hangers or supports 15, 16, for said tube, caps 18, 20, provided upon said tube, the former having a screw adjustment thereon with respect to the latter, which is fixedly mounted upon the tube, and roller or ball bearings interposed between said caps and the shaft, adapted to be adjusted by rotating the cap 18, substantially as described.

2. The combination, with a shaft 13, of a tube 17 surrounding the same, hangers or supports 15, 16, for said tube, caps 18, 20, provided upon said tube, said cap 18 being split and having a screw adjustment upon the tube, and cap 20 being fixedly mounted thereon, roller or ball bearings interposed between the said caps and the shaft, adapted to be adjusted by the rotation of cap 18 upon its screw-thread, and means for clamping said cap 18 in its position of adjustment upon the shaft, substantially as described.

3. In a frame for vehicles, the combination, with a shaft 13, of a tube or sleeve 17 surrounding the same, brackets or supports for said sleeve, caps 18, 20, provided upon the said sleeve, the former having a screw adjustment thereon and having a split portion extending within one of the brackets or supports, and the latter being fixedly mounted with respect to the sleeve, roller or ball bearings interposed between said caps and the shaft, adapted to be adjusted by the rotation of cap 18 on its screw-thread, and means provided upon one of said supports for clamping the cap 18 in its position of adjustment, substantially as described.

4. In a vehicle-truck, the combination, with longitudinal tubular members extending the entire length of the frame and suitably united at one end of the frame, of two transverse tubular members extending the entire width of the frame uniting the said longitudinal members at the other end of the frame, V-shaped hangers extending downwardly from said transverse member and serving to support a vehicle-shaft at their lower ends, sleeves 17 secured in position by said hangers, a vehicle-shaft passing through said sleeves, and bearings interposed between the sleeves and the shaft, substantially as described.

5. In a vehicle-truck, the combination, with longitudinal tubular members extending the entire length of the frame and suitably united at one end of the frame, of two transverse tubular members extending the entire width of the frame uniting the said longitudinal members at the other end of the frame, V-shaped hangers disposed upon either side of each of said longitudinal members and extending downwardly from the transverse members, said hangers serving to support a vehicle-shaft at their lower ends, sleeves 17 secured in position by said hangers, a vehicle-shaft passing through said sleeves, and bearings interposed between the sleeves and the shaft, substantially as described.

6. In a vehicle of the class described, the combination, with longitudinal shafts 7, 7', for supporting the wheels of the vehicle, of a mounting for each of said shafts, permitting them to rotate substantially in horizontal planes, link mechanism uniting said shafts, whereby they are caused to rotate in unison, a steering-rod 42, a bracket or extension 41 carried by said steering-rod, a controlling-lever 43 pivoted to said bracket and adapted to be swung or rotated in two different planes, a link 45 connecting the

steering-rod with the guide-wheels, whereby upon the movement of the lever in one plane the guiding-wheels of the vehicle are controlled as to their lines of travel, braking mechanism, and a flexible cord or member extending over idlers connecting said braking mechanism and lever, whereby upon the movement of the lever in the longitudinal plane said braking mechanism is actuated through the medium of the cord, substantially as described.

7. The combination with a driving friction-disk 37, of a longitudinally-movable friction wheel 24 whose periphery engages or is adapted to engage the friction-disk, means for shifting the latter wheel longitudinally, a segmental rocker-arm 22, and cords united at their ends with the periphery of the rocker-arm and with the said means, the rocker-arm thereby being adapted by its movement in alternative directions to move the wheel 24 longitudinally in alternative directions, whereby the speed of the said wheel may be varied and reversed as desired, substantially as described.

8. The combination with a driving friction-disk 37, of a longitudinally-movable friction wheel 24 whose periphery engages or is adapted to engage the friction-disk, means for shifting the latter wheel longitudinally, a segmental rocker-arm 22, cords united at their ends with the periphery of the rocker-arm and with the said means, the rocker-arm thereby being adapted by its movement in alternative directions to move the wheel 24 longitudinally in alternative directions, whereby the speed of the said wheel may be varied and reversed as desired, a sectional shaft surrounded by the friction-wheel 24, and a differential coupling uniting the sections of said shaft and interposed between the same and the said wheel 24, substantially as described.

9. The combination with a shaft, of a sleeve surrounding the same, a cap 18, an extended portion thereof is provided with slots, said extended portion having threaded engagement with said sleeve, a clamp engaging the extended portion and adapted to secure the same in its threaded engagement with the sleeve, and a bearing interposed between the cap and the shaft, substantially as described.

10. The combination with a shaft, of a sleeve surrounding the same, a cap 18, an extended portion thereof is provided with slots, said extended portion having threaded engagement with said sleeve, a flange for the shaft having clamping engagement with said extended portion of the cap and adapted to secure the same in its threaded engagement with the sleeve, and a bearing interposed between the cap and the shaft, substantially as described.

11. In a vehicle-truck, the combination with transverse members 8 8, of downwardly-extending members 10 10 converging at their outer ends and located beneath the transverse members, a king-bolt disposed longitudinally of the vehicle and pivoted to the latter members with the first-mentioned members, vertical bearings 6 6 united by said members 10 10, a member 9 disposed below the members 10 10 and also uniting the bearings 6 6, individual shafts 7 7 provided with vertical extensions located within the bearings 6 6, and steering mechanism for rotating the said individual shafts in their bearings, substantially as described.

12. In a vehicle, the combination with a driving-shaft formed in sections, of a differential coupling uniting said sections, an elongated portion rotatable with the differential coupling, a wheel 24 including the shaft and engaging and movable longitudinally of the elongated portion, a motor for rotating said wheel, the speed of which wheel is controlled by its longitudinal position with relation to the said portion, and means for shifting the said wheel longitudinally of the said portion, substantially as described.

13. In a vehicle, the combination with a driving-shaft formed in sections, of a differential coupling uniting said sections, an elongated portion rotatable with the differential coupling, a wheel 24 including the shaft and engaging and movable longitudinally of the elongated portion, a driving-disk 37 engaging or adapted to engage the periphery of the wheel 24, the speed of which latter wheel is controlled by its position relative to the center of the disk 37, and means for moving the wheel 24 longitudinally of said elongated portion, substantially as described.

14. In a vehicle, the combination with a driving-shaft formed in sections, of a differential coupling uniting said sections, an elongated portion rotatable with the differential coupling, a wheel 24 including the said portion and shaft and engaging and movable longitudinally of the elongated portion, a driving-disk 37 engaging or adapted to engage the periphery of the wheel 24, the speed of which latter wheel is controlled by its position relative to the center of the disk 37, and means for driving the wheel 24 longitudinally of said elongated portion, substantially as described.

15. In a vehicle, the combination with a driving-shaft formed in sections, of a differential coupling uniting said sections, an elongated housing rotatable with the differential coupling, a wheel 24 including the said housing and shaft and engaging and movable longitudinally of the elongated housing, a driving-disk 37 engaging or adapted to engage the periphery of the wheel 24, the speed of which latter wheel is controlled by its position relative to the center of the disk 37, and means for driving the

wheel 24 longitudinally of said elongated housing, substantially as described.

16. In a friction-wheel, the combination with an annularly-grooved rim of the wheel provided with a central annular slot through the rim, of a series of clamps located about the rim of the wheel, and an annular strip or strips of friction material located in the groove of the rim and secured in place by the said clamps, substantially as described.

696,597. DOMESTIC SWITCH AND FLOW RECEPTACLE BOX. PAUL J. KIMBLE, New York, N. Y. Filed May 1, 1901. Serial No. 54,390. (No model.)

Claim.—1. The combination with an insulating box and a switch therein having an actuating-arm 20, of the cap 23 having arm 27 and provided on its periphery with a pawl 22, a nipple 9 adapted to receive said cap and formed internally with a shoulder for the engagement of said pawl, and means for rotating said cap in said nipple.

2. The combination with an insulating box and switch therein having an actuating-arm 20, of the cap 23 having arm 27 and provided on its periphery with the pawl 22, and having the slot 26 in its bottom, a nipple 9 adapted to receive said cap formed internally with a shoulder for the engagement of said pawl, a washer 33 having pawl projection 37 disposed within said cap, nut 11 on said nipple and actuating-rod 29 having its bearing in said nut and engaging with said washer 33.

3. The combination with a box having insides within it an insulating-base and contacts and provided with a threaded nipple, of a shouldered plug of insulating material adapted to enter said nipple and to be seated upon said base, contact-plugs on said plug adapted to make electrical connection with said contacts when said plug is seated as aforesaid and a flanged nut adapted to engage with said nipple and to have a bearing on the shoulder of said plug.

4. The combination with the box 4 having the threaded nipple 10, of the base 20, spring-clip 43 thereon, plug 36 having contact-plugs 41, and nut 12 adapted to engage with said nipple 10 and with a shoulder on said plug.

5. The combination with a box 4 having the cover 7 and threaded nipple 10, of the base 20, spring-clip 43 on said base, plug 36 having contact-plugs 41 and provided with the screw 45, nut 12 adapted to engage with said nipple 10 and with a shoulder on said plug, and projection 49 on cover 7 adapted to enter the screw 45.

6. The combination with a box, a rotary switch therein, an actuating-rod for rotating said switch and a handle on said rod exterior to said box, of two ratchet-and-pawl mechanism interposed between said rod and said switch; the said mechanism being constructed and arranged so that when one of said ratchets is free to rotate the other is held from rotation by its pawl.

696,598. COIN-CONTROLLED WEIGHING-MACHINE. GURAV F. W. HUGHES, Berkeley, Cal. Filed Oct. 21, 1901. Serial No. 78,549. (No model.)

Claim.—1. In a weighing-machine, the combination with the weighing mechanism thereof, of means whereby the user of the machine may register a guess as to weight, and coin-estimated mechanism by means of which the coin deposited within the machine is returned to the user thereof in case the registered guess as to weight corresponds with that indicated by the weighing mechanism.

2. In a weighing-machine, the combination with the weighing mechanism thereof, of means whereby the user of the machine may register a guess as to weight, coin-estimated mechanism whereby the coin deposited within the machine is returned to the user thereof provided the registered guess as to weight corresponds with that indicated by the weighing mechanism and device whereby the registering means are automatically locked against movement after a coin is deposited and released by the machine being relieved of the user's weight.

3. In a weighing-machine, the combination of a normally concealed weight-indicator, a separate indicator under the control of the user adapted to be set to his estimate or guess of his weight, mechanism for exposing the normally concealed weight-indicator, and mechanism controlled by the deposit of a coin for retaining the coin within the machine, or delivering it exteriorly according to diversity or coincidence between the weight and estimate.

ing it exteriorly according to diversity or coincidence between the weight and estimate.

4. In a weighing-machine, the combination of a weight-indicator, a separate indicator under the control of the user adapted to be set to his estimate or guess of his weight, and mechanism controlled by the deposit of a coin for retaining the coin within the machine, or delivering it exteriorly according to diversity or coincidence between the weight and estimate.

5. In a weighing-machine, the combination of a normally concealed weight-indicator, a separate indicator under the control of the user, adapted to be set to his estimate or guess of his weight, and mechanism controlled by the deposit of a coin for exposing the normally concealed weight-indicator and retaining the coin within the machine or delivering it exteriorly, according to diversity or coincidence between the weight and estimate.

6. In a coin-estimated weighing-machine, means whereby the user of the machine may register a guess as to weight, and mechanism whereby the coin deposited within the machine is returned to the user thereof provided the registered guess as to weight corresponds with that indicated by the machine.

7. In a coin-estimated weighing-machine, means whereby the user of the machine may register a guess as to weight, and mechanism whereby the coin deposited within the machine is automatically returned to the user thereof provided the registered guess as to weight corresponds with that indicated by the machine.

8. A weighing-machine comprising a scale-dial, means whereby the user of the machine may register a guess as to weight, and coin-estimated mechanism connected with the registering means whereby the coin deposited within the machine is returned to the user thereof provided the registered guess as to weight corresponds with the weight as indicated by the scale-dial.

9. A weighing-machine comprising a scale-dial connected with and actuated by the movement of the scale-platform, means whereby the user of the machine may register a guess as to weight, coin-estimated mechanism whereby the coin deposited within the machine is returned to the user thereof provided the registered guess as to weight corresponds with the weight as indicated by the scale-dial, and device for automatically locking the registering means after a coin has been deposited within the machine.

10. In a weighing-machine, the combination of a scale-dial, means for operating it by the imposition of the user's weight, a set dial under the control of the user adapted to indicate his estimate or guess of his weight, a connection between the two dials adapted to be made or broken by their relative positions dependent upon the coincidence or diversity between the weights indicated, and coin-controlled mechanism adapted, according to said coincidence or diversity, to deliver the coin exteriorly, or to retain it within the machine.

11. In a weighing-machine, the combination of a normally concealed scale-dial, means for operating it by the imposition of the user's weight, a set dial under the control of the user adapted to indicate his estimate or guess of his weight, a connection between the two dials adapted to be made or broken by their relative positions dependent upon the coincidence or diversity between the weights indicated, and mechanism actuated by a deposited coin for exposing the normally concealed dial, and to deliver said coin exteriorly or retain it within the machine, according to the coincidence or diversity in the positions of the two dials.

12. In a weighing-machine, the combination of a scale-dial adapted to be operated by the imposition of the user's weight, a set dial under control of the user and adapted to indicate his estimate or guess of his weight, an electric circuit including contacts on the dial which make or break connection according to whether the dials coincide or differ in relative position, and mechanism operated by the deposited coin for completing said electric circuit.

13. In a weighing-machine, the combination of a scale-dial adapted to be operated by the imposition of the user's weight, a set dial under control of the user and adapted to indicate his estimate or guess of his weight, an electric circuit including contacts on the dial which make or break connection according to whether the dials coincide or differ in relative position, and mechanism operated by the deposited coin for completing said electric circuit and delivering the coin exteriorly or retaining it within the machine according to the coincidence or diversity of the dials.

14. In a weighing-machine, the combination of a normally concealed scale-dial adapted to be operated by the imposition of the user's weight, a set dial under control of the user and adapted to indicate his estimate or guess of his weight, an electric circuit including contacts on the dial which make or break connection according to whether the dials coincide or differ in relative position, and mechanism operated by the deposited coin for exposing the normally concealed scale-dial, completing said electric circuit and delivering the coin exteriorly or retaining it within the machine according to the coincidence or diversity of the dials.

15. In a weighing-machine, the combination with a scale-dial, of a set dial arranged in advance thereof and adapted to be turned by the user of the machine to register a guess as to weight, a coin-runway for the reception of a coin in payment for the use of the machine, a coin-tube, means for receiving the coin from the runway and delivering same into the coin-tube, a deflecting-gate working within the coin-tube, and electrical means whereby said gate is thrown to open the coin-tube when the set dial indicates the same number as the scale-dial or as to permit of the coin returning to the user of the machine.

16. The combination with the scale weighing mechanism, of means operated by the user of the machine whereby a guess as to weight may be registered, of coin-estimated mechanism by means of which the coin deposited within the machine is returned to the user thereof in case the registered guess as to weight corresponds with that indicated by the weighing mechanism, and electrical connection between the registering means, the coin-estimated mechanism whereby the circuit is completed and the coin released for return to the user of the machine when the registered guess corresponds with the weight indicated by the weighing mechanism.

17. The combination with the scale weighing mechanism, of a shutter by means of which the number indicative of the person's weight is hidden from view, device whereby the shutter is automatically released as to its lift and expose the weight-number by a coin deposited within the machine, means operated by the user of the machine to register a guess as to weight, and mechanism whereby the deposited coin is returned to the user of the machine provided the registered guess corresponds with the weight indicated by the scale mechanism.

696,599. ELECTRIC WATER-HEATER. MILTON H. SAUNDERS and ERNEST LEVI, San Francisco, Cal. Filed Apr. 10, 1901. Serial No. 54,116. (No model.)

Claim.—1. The combination in an electrical heater of a pipe having legs of unequal length one of said legs serving as a water-inlet and the other as a water-outlet and outlet having a controlling-cock; an electric insulator for said pipe; a coil of wire having high resistance, wound in contact with the insulating-surface; clamps extending between the legs of the pipe, having one end to secure the ends of the coil against the insulating-surface and the other end extending to and clamped against and insulated from the opposite leg of the coil; and electrical connections with the coil.

2. An electrical water-heater, consisting of a pipe, an insulating enclosing material, a electric coil of high-resistance wire, wound in contact with the insulating-covered pipe, a supply through which water is delivered into one end of said pipe, and a controlled discharge from the opposite end, clamps, one end of which secure the ends of the coil against

the insulating-surface, the opposite ends clamping the supply-pipe and having an insulating material between them and the supply-pipe screws by which said clamps are fixed or loosened, an electrical connection with the coil whereby an electrical current of high tension is passed through the coil, and the latter protected by the water-conducting pipe which it incloses.

3. The combination is an electrical heater of a reservoir, a U-shaped pipe having legs of unequal length, the open ends of which connect with the interior of the reservoir, one above the other, an insulating-covering for the longer arm, a coil of high resistance wound in contact with said covering and inclosing the pipe, plates extending between the legs of the pipe and having opposite ends insulated therefrom one of said ends securing the ends of the coil, and screws engaging the plates between their ends, and electrical connections through which an electrical circuit is established through the coil whereby a circulation of water is produced within the coil and reservoir, and a discharge-pipe connecting with the heating pipe.

4. A water-heater consisting of a U-shaped pipe, the upper ends of which extend into a reservoir, one of said ends projecting above the other, an inlet-pipe connecting with the shorter branch, and a discharge-cock with the longer branch, the thin mica casing surrounding the pipe, a single coil of high-resistance wire wound upon said insulating-covering with the turns out of contact with each other, clamps extending between the tops of the pipe, having one end to secure the ends of the coil against the mica and the other end extending to and clamped against, and insulated from, the opposite leg of the coil, and connections by which an electrical circuit through the wire is completed.

696,600. CAMERA. HERMAN L. SILVER, Los Angeles, Cal. Filed Oct. 28, 1901. Serial No. 89,399. (No model.)

Claim.—1. In a camera, the combination of a pair of standards, a camera-front covered in said standards, means for linearly adjusting the lens and camera-front upon the standards, means for maintaining the linear direction during said adjustment and means for swinging the camera-front.

2. In a camera, the combination of standards, means for adjustably cutting the lens and camera-front upon the standards in a linear-vertical plane, means for maintaining the linear direction during said adjustment and means for swinging the front in a vertical plane.

3. In a camera, the combination of a pair of standards, a camera-front carried thereby, a plurality of pin-and-dot connections upon each side of the camera-front, means for linearly adjusting the lens and camera-front upon the standards, means for maintaining the linear direction during said adjustment and means for swinging the camera-front.

4. In a camera, the combination of a pair of standards, a camera-front carried thereby, a plurality of pin-and-dot connections upon each side of the camera-front for linearly adjusting the lens and camera-front upon the standards, means for maintaining the linear direction during the linear adjustment, means for swinging the camera-front, and latches carried by the camera-front adapted to engage and disengage the standards.

5. In a camera, the combination of a pair of standards, a camera-front carried thereby, a plurality of pin-and-dot connections upon each side of the camera-front for linearly and radially adjusting the same, latches engaging the standards and a cam device for operating the latches.

696,601. EXHAUST-HEAD. HENRY SHAW, JR., Pitt. Filed July 28, 1901. Serial No. 89,373. (No model.)

Claim.—1. The combination is an exhaust-head, of an inclosed shell, an outlet-pipe in the upper end thereof, an inlet-pipe in the central portion of the lower head thereof closed at its upper end and having lateral openings therein, spiral-shaped wings extending from said openings as to form spiral passages therefrom, and vertical ribs or wings on the inside surface of said shell opposite said spiral passages, substantially as and for the purpose set forth.

2. The combination is an exhaust-head of an inclosed shell, an exhaust-pipe extending into the lower part of said shell, wings on said exhaust-pipe forming spiral passage-openings therefrom, vertical ribs or wings on the inside of said shell opposite said spiral discharge-openings, an annular deflector having a central opening therein above said vertical ribs, an outlet-pipe on the top of said shell, and an inverted conical deflector on the lower end thereof, substantially as and for the purpose set forth.

696,602. GAME. JOHN R. SHAW, New York, N. Y., assignor to Henry M. Shaw, New York, N. Y. Filed Dec. 24, 1901. Serial No. 87,394. (No model.)

Claim.—1. A game consisting of the combination of a board, a magnet under the surface of the same, smooth magnetic and non-magnetic disks substantially as described.

2. A game consisting of the combination of a board with a smooth even surface, a starting-point and ending-point designated on said board, a magnet interposed between the starting-point and ending-point, and underneath the surface of the board, and magnetic disks and non-magnetic disks, adapted to slide between the starting-point and ending-point, over the magnet, substantially as described.

696,603. CLAMPING-RING FOR PIPE-COUPPLING. FRANK H. SMITH, Bradford, Pa., assignor to Solomon B. Druser, Bradford, Pa. Filed Dec. 11, 1901. Serial No. 81,906. (No model.)

Claim.—1. A sectional clamping-ring having its sections provided with overlapping portions, the adjacent faces of which are provided with interlocking alining devices having cam-faces, adapted to draw the sections into proper relative positions when forced together, substantially as described.

2. A sectional clamping-ring having its sections provided with overlapping portions, the inner faces of which are provided the one with an alining-recess and the other with an alining projection, said recess and projection having mating faces inclined to the plane of the ring, and adapted to draw the sections of the ring into proper relative positions when forced together, substantially as described.

3. A sectional clamping-ring having its sections provided with overlapping portions, the inner faces of which are provided with a projecting rib and recess respectively, formed V-shaped in cross-section, and adapted to draw the sections into proper relative positions when forced together, substantially as described.

4. A sectional clamping-ring having its sections provided with overlapping portions, the inner faces of which are provided with a radially-disposed rib, and a radially-disposed recess respectively, having faces inclined to the plane of the ring and adapted to draw the sections of the ring into proper relative positions when forced together, substantially as described.

5. A sectional clamping-ring having its sections provided with overlapping portions, the inner faces of which are provided the one with an alining-rib and the other with an alining-recess, said rib and recess have faces inclined to the plane of the ring and adapted to draw the sections into proper relative position when forced together, said overlapping portions being also provided the one with a retaining-rod and the other with a recess for loosely engaging the same to retain the sections of the ring together temporarily, substantially as described.

696,604. ORB-CONCENTRATOR. ALBERT H. BRUNSON, Little Rock, Ark. Filed June 28, 1900. Serial No. 81,612. (No model.)

Claim.—1. In an orb-concentrator, the combination of a plurality of stationary drums arranged in series and connected end to end, an inlet for introducing ore or the like into the first drum of said series of drums, and means tangential to the drums for introducing a separate or independent blast of air or other fluid into each of said drums to thereby cause the

material contained in the drums to travel in circular paths within the same.

2. In an orb-concentrator, the combination of a plurality of drums arranged in series and connected end to end, an inlet for introducing ore or the like into the first of the series of drums and means for introducing a separate or independent blast of air or other fluid tangentially into each of said drums to cause the material therein to travel in circular paths within the drums.

3. In an orb-concentrator, the combination of a plurality of drums arranged in series and connected end to end, an inlet for introducing ore or the like into the first of the series of drums, means for introducing a separate or independent blast of air or other fluid tangentially into each of said drums throughout the length thereof and provisions for varying the force of the blast in the different drums of the series.

4. In an orb-concentrator, the combination of a plurality of drums of different sizes arranged in series, the end of one drum being connected to the end of the next larger drum of the series, an inlet for introducing ore or the like to the said series of drums, and means tangential to the drums for introducing separately into each drum an independent blast of air or other fluid to cause the material to circulate in curved paths within each of said drums at desired velocities.

5. In an orb-concentrator, the combination of a plurality of drums of varying size arranged in series and connected end to end, each of said drums being provided with a concentrate-box and an outlet for the concentrate leading to said box, an inlet for introducing ore or the like to the first drum of said series of drums, and means for producing gyratory currents of air or other fluid in said drums.

6. In an orb-concentrator, the combination of a plurality of drums arranged in series and connected end to end, a flange partially closing the opening leading from one drum to the next adjacent drum, means for introducing ore or the like into the end drum of the series and means for separately introducing a blast of air or other fluid into the different drums of the series.

7. In an orb-concentrator, the combination of a plurality of drums arranged in series and connected end to end, said drums varying in size from end to end of the series, means for feeding ore into the first of the series of drums, means tangential to the drums for introducing a blast of air or other fluid into each of said drums and devices for regulating the force of the blast in each drum.

8. In an orb-concentrator, the combination of a plurality of drums arranged in series and connected end to end, said drums progressively varying in size from end to end of the series, means for feeding ore at the like into the end drum of the series, an air or fluid inlet to each of said drums, said inlet varying in size inversely as the size of the drum and a discharge-outlet for said drums.

9. In an orb-concentrator, the combination of a plurality of drums arranged in series and having open end connections, a separate air or fluid inlet for each of said drums extending substantially the length thereof and

tangential thereto, means for feeding ore to the first of said drums, and a discharge-opening for the concentrates in each of said drums.

10. In an ore-concentrator, the combination of a plurality of drums arranged in series and having open end connections, a flange partially closing the opening leading from one drum to the next adjacent drum, a discharge-opening for the concentrates in each of said drums, and means substantially tangential to the drums for introducing a blast of air or other fluid into each of said drums across the said discharge-opening thereto.

11. In an ore-concentrator, the combination of a plurality of drums arranged in series and having open end connections, said drums varying progressively in size from end to end of the series, means for introducing ore or like material to the first drum of the series, a discharge-opening for the concentrates in each drum, an axial exit for the light impurities separated from the valuable particles, and means for introducing tangential air or fluid currents into each of said drums.

12. In an ore-concentrator, the combination of a drum, a discharge-opening formed in the wall of said drum, a normally closed door for covering said opening and on which the valves or concentrates may rest, said door being counterbalanced to automatically discharge the concentrates that collect thereon, an air or fluid inlet extending lengthwise of the drum and arranged tangential thereto to direct a blast directly upon and over said door to thereby subject the concentrates or valves to a strong fluid current prior to their being discharged.

696,605. ORE-CONCENTRATOR. ALBERT H. STEINER, ILLINOIS.
Recd. Art. Filed July 14, 1900. Serial No. 28,021. (No model.)

Claim.—1. In an ore-concentrator, the combination of a plurality of independent compartments similarly arranged in series, an inlet and central outlet for each of said compartments, a discharge-opening for the concentrates near the bottom of each compartment and a concentrate-box in communication with said discharge-opening, means for introducing a blast of air or other fluid through the inlet of the first compartment of the series and tangential thereto, the inlet of each of the remaining compartments being tangentially arranged and in communication with the central outlet of the next preceding compartment.

2. In an ore-concentrator, the combination of a plurality of drums similarly arranged in series, means for introducing a blast of air or other fluid into the first drum of the series, a tangential inlet and a central outlet for each of said drums to cause the particles to travel in circular paths and the heavier particles to be separated or thrown from the lighter particles, which latter pass into the central outlet, the central outlet of each of said drums being connected to the tangential inlet of the next succeeding drum of the series.

3. In an ore-concentrator, the combination of a plurality of drums similarly arranged in series, means for introducing a blast of air or other fluid into the first drum of the series, a central outlet for each of said drums, a tangential inlet extending substantially the length of and for each

of said drums to cause the particles to travel in circular paths and the heavier particles to be separated or thrown from the lighter particles which latter pass through the central outlet, the central outlet of said drums being in communication with the tangential inlet of the next succeeding drum of the series.

4. In an ore-concentrator, the combination of a plurality of drums similarly arranged in series and progressively varying in size from one end of the series to the other, an outlet and an air or fluid tangential inlet for each of said drums, means for introducing a blast of air or fluid into the first drum of the series to cause the particles to travel in circular paths and the heavier to be separated or thrown from the lighter particles which latter pass to the central outlet, and connections between the drums to successively carry the said blast of air or fluid from the first drum tangentially into the succeeding larger drums and a discharge-opening for the concentrates in the bottom of said drums.

5. In an ore-concentrator, a plurality of independent drums similarly arranged in series, said drums gradually increasing in size from the beginning to the end of the series, a feed-hopper connected to the first drum of the series, means for introducing a blast of air or other fluid into said first drum of the series to cause the particles to travel in circular paths, and connections between the drums for discharging the air or fluid currents and the particles carried thereby directly from each drum tangentially into the next succeeding larger drum.

6. In an ore-concentrator, a series of drums, an air-iplut for directing a blast into the first drum of the series, a feed-hopper for said series of drums connected to said blast-inlet, said hopper comprising an open-mouth upper portion, and downwardly-divergent walls to prevent choking of the hopper, a regulating device to which said walls are connected, and wings projecting from the walls of said device toward each other to partially close the opening between the lower ends of the said divergent walls.

7. In an ore-concentrator, the combination of a plurality of drums of different sizes arranged in series, an inlet for directing a blast of air tangentially into the first drum of the series, a feed-hopper for said series of drums connected to said blast-inlet, the same comprising an open-mouth portion and downwardly-divergent walls, a regulating device into which said walls project, wings projecting from the sides of said device toward each other to partially close the opening between the divergent walls, and slides fitted to the upper and lower ends of said divergent walls to regulate the material passing.

8. In an ore-concentrator, a plurality of drums arranged in series, a tangential inlet, a central outlet, and discharge-opening for each of said drums, the central outlet of each drum being connected to the tangential inlet of the next succeeding drum of the series to direct a current of air or other fluid over the discharge-opening in the wall of said drums to thereby carry material seeking to settle on said wall above and over the discharge-opening, and means to introduce a blast of air or other fluid into the first drum of the series.

696,606. ORE-CONCENTRATOR. ALBERT H. STEINER, ILLINOIS.
Recd. Art. Filed Oct. 22, 1900. Serial No. 24,768. (No model.)

Claim.—1. In an ore-concentrator, the combination of a funnel-shaped increment of gradually-increasing cross-sectional area from one end to the other, said increment being closed at its smaller end, a feed-hopper leading into the funnel-shaped increment at its smaller end, a fluid-distributing chute tangentially arranged with reference to said increment and leading into the same, an outlet for the concentrates, located in the wall of the increment above the lowest portion thereof, and a series of concentrate-bins in communication with said outlet, whereby as material fed into the increment at its smaller end is given a spiral or gyratory motion within the increment and moved toward the larger end thereof, the concentrates or heavier particles are subjected to decreased fluid-currents and pass through the outlet into the concentrate-bins according to their specific gravity.

2. In an ore-concentrator, the combination of an increment of gradually-increasing cross-sectional area from one end to the other, said increment being closed at its smaller end, an air-distributing chute tangentially arranged with reference to said increment extending substantially the length of said increment and leading into the same, an outlet for the concentrates, and a series of concentrate-bins in communication with said outlet.

3. In an ore-concentrator, the combination of a funnel-shaped increment of gradually-increasing cross-sectional area from one end to the other, said increment being closed at its smaller end, means to feed material into said increment, a distributing-pipe, a fluid-distributing chute connected to said pipe and extending substantially the length of said increment and being tangentially connected thereto to produce within said increment circular fluid-currents, and an outlet for the concentrates.

4. In an ore-concentrator, the combination of a funnel-shaped increment of gradually-increasing cross-sectional area from one end to the other, said increment being closed at its smaller end, means to feed material into said increment, a distributing-pipe and a fluid-distributing chute extending substantially the length of said increment and the chute being arranged tangential thereto, a discharge-outlet for the concentrates extending substantially the length of the increment and a series of concentrate-bins in communication with said outlet.

5. In an ore-concentrator, the combination of a funnel-shaped increment of gradually-increasing cross-sectional area from one end to the other, said increment being closed at its smaller end, means to feed material into said increment, a distributing-pipe and a fluid-distributing chute extending substantially the length of said increment, and the chute being arranged tangential thereto, a discharge-outlet for the concentrates arranged in the wall of the increment above the bottom thereof and opposite the distributing-chute.

6. In an ore-concentrator, the combination of a funnel-shaped increment of gradually-increasing cross-sectional area from one end to the other and having a supporting-incline, means for feeding material into said increment near the smaller end thereof, a distributing-pipe, a distributing-chute connected thereto and arranged tangentially to the increment to direct a blast of air directly onto and over the supporting-incline thereof, a discharge-outlet arranged in the wall of the increment above the supporting-incline and on the side thereof opposite the distributing-chute.

7. In an ore-concentrator, the combination of a funnel-shaped increment of gradually-increasing cross-sectional area from one end to the other and having a supporting-incline, a distributing-pipe and a distributing-chute extending substantially the length of said increment, the said chute being connected tangentially thereto to direct a blast of air onto the said supporting-incline, a discharge-outlet in the wall of the increment opposite the distributing-chute and a series of concentrate-bins in communication with the said outlet.

8. In an ore-concentrator, the combination of a funnel-shaped increment of gradually-increasing cross-sectional area from one end to the other and having a supporting-incline, a distributing-pipe and a distributing-chute extending substantially the length of said increment, the said chute being connected tangentially thereto to direct a blast of air onto the said supporting-incline, a discharge-outlet in the wall of the increment opposite the distributing-chute, and a series of concentrate-bins, said outlet having flanges projecting into the concentrate-bins.

9. In an ore-concentrator, the combination of a funnel-shaped increment of gradually-increasing cross-sectional area from one end to the other and having a supporting-incline, a distributing-pipe and a distributing-chute extending substantially the length of said increment, the said chute being connected tangentially thereto to direct a blast of air onto the said supporting-incline, a discharge-outlet in the wall of the increment opposite the distributing-chute, and a series of concentrate-bins having self-closing and normally closed doors, said outlet having flanges projecting into the concentrate-bins.

10. In an ore-concentrator, the combination of a funnel-shaped increment of gradually-increasing cross-sectional area from one end to the other and having a supporting-incline, a distributing-pipe and a distributing-chute extending substantially the length of the increment, the said chute having partitions therein and connected tangentially to the in-

crement to direct a blast of air onto the said supporting-incline, a discharge-outlet in the side wall of the increment opposite the distributing-chute and a series of concentrate-bins in communication with said outlet.

11. In an ore-concentrator, the combination of a funnel-shaped increment of gradually-increasing cross-sectional area from one end to the other and having a supporting-incline, a distributing-pipe and a distributing-chute extending substantially the length of the increment, the said chute having partitions therein and connected tangentially to the increment to direct a blast of air onto the said supporting-incline, a discharge-outlet in the side wall of the increment opposite the distributing-chute, a series of flanges projecting inward from the wall of the funnel and a series of concentrate-bins in communication with said outlet.

12. In an ore-concentrator, the combination of an increment of gradually-increasing cross-sectional area from one end to the other and having a supporting-incline, means for feeding material into the same near the smaller end thereof, a fluid-distributing chute connected thereto and arranged tangentially to the increment to direct a fluid-blast directly onto and over the supporting-incline, and a discharge-opening in the wall of the increment opposite the tangential inlet and above the supporting-incline so that material falling down the wall of the increment after being projected above the discharge-opening by the incoming blast will pass through said discharge-opening.

696,607. HEATING-FURNACE. MATTHEW H. SMITH and RALPH GOSWELL, JR., ILLINOIS. Filed Apr. 4, 1901. Serial No. 24,804. (No model.)

Claim.—1. In a furnace for heating blooms or other pieces of metal, the combination with a preheating chamber or hearth, and means whereby the blooms or other pieces may be moved along said hearth, of a finishing chamber or hearth situated laterally of the preheating chamber or hearth, and a connection between said chambers or hearths through which the blooms or other pieces may be transferred from the preheating to the finishing chamber or hearth by lateral movement.

2. The combination with a preheating furnace or chamber for blooms and other pieces of metal, and means for advancing the blooms or other pieces in contiguous succession through said furnace or chamber, of a finishing-hearth situated to one side of the delivery end of said furnace or chamber, and means for transferring the blooms or pieces to said hearth by endwise movement.

3. In a furnace for heating blooms or other pieces of metal, the combination with a preheating bed or hearth, and means for moving the blooms or other pieces along said bed or hearth, of a finishing-hearth located to one side of the preheating chamber or hearth and communicating therewith, and means for transferring the blooms or other pieces from the preheating bed or hearth to the finishing-hearth by a movement thereof in a direction substantially at right angles to their movement along the said bed.

4. In a heating-furnace of the class described, the combination with a furnace or chamber having an inclined bed of water-cooled pipes extending the full length thereof, and means whereby the pieces to be heated may be pushed along said bed, of a finishing-hearth located to one side of the lower end portion of said bed and communicating therewith.

5. In a heating-furnace for blooms and the like, a preheating-chamber adapted to receive the blooms or other pieces transversely thereof, and a finishing-hearth extending at right angles thereto and communicating therewith.

6. In a heating-furnace of the class described, a preheating-chamber and means for advancing the pieces to be heated in contiguous succession through said chamber, a finishing-hearth communicating therewith and extending at right angles thereto, and a pushing device for transferring the blooms from the chamber to the hearth by endwise movement.

7. In a heating-furnace of the class described, the combination of a preheating-chamber having therein a water-cooled bed and means for advancing the pieces to be heated in contiguous succession along said bed, a side door in said furnace opposite the lower portion of said bed, a finishing-hearth on the opposite side of the bed from the said door and communicating with said chamber, and a pushing device operative through said door and transversely across the said bed.

8. In a heating-furnace of the class described, the combination of a preheating-chamber, having an inclined bed and means whereby the pieces to be heated may be moved along said bed, a side door in the furnace opposite the said bed, a finishing-hearth on the opposite side of said bed and in line with said door, a pushing device operative through the said door and transversely across the said bed, and means for effecting a longitudinal movement of said pushing device to position it opposite any desired portion of the hearth.

9. In a heating-furnace of the class described, the combination of a preheating-chamber, having an inclined bed and means for advancing the pieces to be heated in contiguous succession along said bed, a finishing-hearth to one side of the lower end of said bed, and fire-chambers upon opposite sides of said hearth and communicating therewith and also with the preheating-chamber.

10. In a heating-furnace of the class described, the combination of a preheating-chamber, means for advancing the pieces to be heated through said chamber in contiguous succession, a finishing-hearth situated laterally of the delivery end of said chamber, a passage connecting the two, a side door in the furnace opposite the said passage, and a pushing device operative through the said door.

11. In a furnace for heating blooms and other pieces of metal, a preheating furnace or chamber having a transverse width greater than the length of the pieces to be heated, means for advancing the pieces through said furnace or chamber, a finishing-hearth located to one side of one end portion of said furnace or chamber and having the length greater than the length of said pieces, and a passage connecting said hearth with the said furnace or chamber.

696,606. LOCK-HUB. WARREN H. TAYLOR, Stamford, Conn., assignor to The Yale & Towne Manufacturing Company, Stamford, Conn. Filed Apr. 4, 1902. Serial No. 676,426. (No model.)

Claim.—1. The combination of a hub formed with a reduced neck, an angular spindle opening, and a lock-operating arm having a ring fitting around the reduced neck, so that the transverse projection beyond it; the hub being divided in the plane of the ring so that the latter is gripped between the parts of the hub when said parts are held together by the lock-acting, when the hub is in use.

2. The combination of a hub, having transverse, and a reduced neck formed thereon, and an angular spindle opening formed therein, the hub being divided through the reduced neck to form a neck portion on each part of the hub; and a lock-operating arm having a ring fitting around both portions of the reduced neck, and having a central portion 5 introduced between the hub parts and formed with a spindle opening.

696,609. SODIUM-ACID ETHER OF CINCHONA ALKALOIDS. HERMANN THIER, Frankfurt-on-the-Main, Germany, assignor to Farbwerke Hoechst AG, Frankfurt-on-the-Main, Germany. Original application filed Apr. 24, 1901, Serial No. 57,283. Divided and this application filed Jan. 8, 1902. Serial No. 66,988. (No specimens.)

Claim.—1. The herein-described new sodium-acid ether of the cinchona alkaloids being very difficultly soluble in water, readily soluble in alcohol, benzene, ether and chloroform, still possessing basic properties forming with organic and inorganic acids well-characterized salts, substantially as hereinbefore described.

2. The herein-described new sodium-acid ether of quinine having most probably the formula

forming nearly tasteless needles, melting at 97° centrifugally very difficultly soluble in water, readily soluble in alcohol, benzene, ether and chloroform; forming well-characterized salts with organic and inorganic acids, substantially as described herein.

696,610. STOVE FOR THE VENTILATION OF ROOMS OR OTHER PLACES. HANS TUCK, Brussels, Belgium. Filed Oct. 22, 1901. Serial No. 73,611. (No model.)

Claim.—In a heating apparatus, the combination, with a grate, of tubes forming with said grate a fuel-container and open at one end to the atmosphere, a chamber arranged above and communicating with said fuel-container, another chamber communicating with said tubes at their other ends and having a discharge, said first-named chamber having an opening communicating with the atmosphere and a smoke-discharge, and a movable hollow device constituting a closure for said opening and having an opening to the atmosphere and also an opening adapted to register with the discharge-opening of said other chamber, substantially as described.

696,611. COPY-FREED APPARATUS FOR SALE OF STAMPS, TICKETS, OR THE LIKE. KARL UHRENBACH, Christiansburg, Norway. Filed Mar. 20, 1901. Serial No. 58,081. (No model.)

Claim.—1. In an apparatus for the sale of tickets and the like, the combination with a suitable case, a stationary and a movable knife, of means for delivering a continuous strip between said knives, a receptacle for the delivered portion of said strip, a lid for said receptacle, and means thereon to operate the movable knife to cut off the strip, substantially as set forth.

2. In an apparatus for the sale of tickets and the like, the combination with a suitable case, a supply-roller and a ticket-strip thereon, of a roller, a grooved roll cooperating therewith and pins in the roller arranged to enter the grooves in the grooved roll operating to feed the strip forward after leaving the supply-roller, a pair of printing and delivery rolls to receive the strip from the aforementioned case, a stationary and a movable cutter, a receptacle for the tickets, a lid therefor, and means on said lid to operate the movable cutter to cut off the end of the strip, substantially as set forth.

3. In an apparatus for the sale of tickets and the like, the combination with a suitable case, a supply-roller and a strip thereon, of a pair of rollers organized to feed the strip forward, a pair of delivery-rolls to receive the strip from the aforementioned case, a stationary and a spring-actuated cutter, a receptacle for the tickets, a pivoted lid therefor and a crank on one of the pivots to operate the spring-actuated cutter toward

the stationary cutter when said lid is opened, thereby severing the ticket from the strip, substantially as set forth.

4. In an apparatus for the sale of tickets and the like, the combination with a suitable case, a supply-roller and a strip thereon, of a pair of rollers to feed the strip forward, a pair of delivery and printing rolls geared to one of the feed-rollers, a receptacle for the tickets, said delivery and printing rolls arranged to deliver the end of the strip into the case, cooperating stationary and reciprocable knives, the latter provided with a slot, a lid, transverse for mounting said lid, a crank on one of them, the pin of said crank entering the slot in the reciprocable knife, whereby the knife is operated to sever the end of the strip when the lid is opened, substantially as set forth.

696,612. MOTOR. JAMES G. WALKER, Waco, Tex. Filed Feb. 14, 1901. Serial No. 47,222. (No model.)

Claim.—1. In a rotary engine, the combination with a cylinder, an engine-shaft, and a piston movable within the cylinder to operate the shaft, of a sliding abutment, induction and exhaust ports disposed at opposite sides of the abutment, a controlling-valve for the induction-ports, rock-shafts having operative relation with the abutment and controlling-valve, respectively, abutment-operating arms and valve-operating arms extending from said shafts, a trip-block movable with the shaft and disposed to contact directly with said arms for the purpose of operating the abutment and controlling-valve in succession, valve-closing arms connected to the valve-operating arms, and means movable with the engine-shaft for operating the valve-closing arms.

2. In a rotary engine, the combination with a cylinder, an engine-shaft, and a piston movable within the cylinder to operate said shaft, of a sliding abutment, induction and exhaust ports at opposite sides thereof, a controlling-valve for the induction-ports, rock-shafts operatively related to the abutment and controlling-valve respectively, operating-arms extending from said rock-shafts, a controlling-disk movable with the engine-shaft, a trip-block fixed to said disk and disposed to contact directly with said arms to operate the abutment and to open the controlling-valve, and a device for effecting the return of the controlling-valve, said device being positioned by centrifugal force.

3. In a rotary engine, the combination with a cylinder, engine-shaft, and piston, of a sliding abutment, induction and exhaust ports, a controlling-valve for the induction-ports, an abutment-operating arm and a valve-operating arm operatively connected respectively with the abutment and controlling-valve, a valve-closing arm disposed beyond the valve-operating arm, and means, movable with the engine-shaft, for operating the several arms in succession.

4. In a rotary engine, the combination with a cylinder, piston, engine-shaft, and the sliding abutment, of a removable front platform formed of a section of the cylinder, a rear platform disposed above and supported by the cylinder, induction and exhaust ports opening into the cylinder, an abutment-acting mechanism mounted on the cylinder between the platforms, and a valve-chest mounted upon the rear platform, abutment-operating mechanism supported on the front platform, and valve-operating mechanism mounted upon the rear platform, a controlling-disk movable with the en-

gine-shaft, and a trip-block carried by said disk and disposed to effect the successive actuation of the abutment and valve operating mechanism.

5. In a rotary engine, the combination with a cylinder, piston, shaft, and sliding abutment, of platforms carried by and disposed above the cylinder, an abutment-acting and a valve-acting mechanism mounted upon the cylinder, abutment-operating mechanism mounted on the cylinder, and valve-operating mechanism supported above the platforms, valve-closing mechanism disposed beyond the valve-operating mechanism and operatively connected therewith, a controlling-disk movable with the shaft and provided with a trip-block disposed to effect the actuation of the abutment-operating mechanism and the valve-operating mechanism in succession, and a centrifugally-operated governor-arm disposed to effect the subsequent actuation of the valve-closing mechanism to effect the automatic cut-off of the motive agent.

6. In a rotary engine, the combination with a cylinder, piston, shaft, and sliding abutment, of a controlling-valve, a valve-operating arm operatively connected therewith, a separately-mounted valve-closing arm having operative connection with the valve-operating arm, and means for operating said arm in succession, said means including a device positioned by centrifugal force and disposed to operate the valve-closing arm.

7. In a rotary engine, the combination with a piston, cylinder, shaft, and sliding abutment, of a rock-shaft having a pair of laterally-extending arms, one of which is operatively related to the abutment, a spring extending laterally from the rock-shaft, and a link having pivotal connection to the fixed part of the engine and to the free end of the spring.

8. In a rotary engine, the combination with a cylinder, piston, shaft, and sliding abutment, of a controlling-valve, a pair of rock-shafts in laterally-opposed relation and provided respectively with a valve-operating arm and a valve-closing arm, means connecting said arms to effect their movement in reverse directions, and means for operatively connecting one of the rock-shafts with the controlling-valve, and means operated by the engine-shaft for operating said arms in succession, said means including a device positioned by centrifugal force and disposed to actuate the valve-closing arm.

9. In a rotary engine, the combination with a plurality of cylinders, pistons, sliding abutments, and a common shaft, of a controlling-disk carried by said shaft, controlling-valves for said cylinders, interlocking rock-shafts operatively connected with the abutments and provided upon their contiguous ends with operating-arms disposed adjacent to the opposite side faces of the controlling-disk, a pair of interlocking rock-shafts having operative relation to the controlling-valves and provided upon their adjacent ends with valve-operating arms, disposed adjacent to the opposite faces of the controlling-disk, and trip-blocks disposed at opposite sides of the disk and designed respectively to effect the successive actuation of the abutment-operating arms and the valve-operating arms.

10. In a rotary engine, the combination with a plurality of cylinders and valve-chests, of a superimposed platform removably carried by the cylinders, abutment-actings also carried by the cylinders, valves located in the valve-chests, sliding abutments disposed to be withdrawn into the abutment-actings, valve-operating mechanism for the several valves and abutment-operating mechanism for the several abutments, said abutment-operating mechanism being mounted on the removable platform, and means for operating said mechanism.

11. In a rotary engine, the combination with pistons, abutments, controlling-valves and a plurality of sectional equivalent cylinders, connected in a rigid organization, of a platform surrounding the cylinders and of sectional form, two of said sections serving to close a series of openings formed in the cylinders, whereby the removability of said platform will permit access to the interior of the cylinders to be gained for purposes of repair.

12. In a rotary engine, the combination with a plurality of cylinders, pistons, sliding abutments, and a common shaft, of a controlling-valve, valve-operating mechanism, abutment-operating mechanism, a controlling-disk, blocks carried by the disk for operating the abutment-operating mechanism, and for moving the valve-operating mechanism in one direction, and a pair of rigidly-connected centrifugally-operated governor-arms loosely mounted on the shaft and operatively related to and movable with the disk and disposed to shift the valve-operating mechanism in the opposite direction.

13. In a controlling device for rotary engines, the combination with the shaft and disk, of spring-retained governor members carried by the disk, bell-crank governor-levers fulcrumed upon the disk and having sliding connection with said members, and a plurality of governor-arms connected with said governor-levers and provided with laterally-disposed terminal fingers.

14. In a controlling device for rotary engines, the combination with a shaft, and a disk having oppositely-disposed annular slots, of spring-retained governor members movable within said slots, bell-crank levers fulcrumed upon the disk and having sliding connection at one end with said members, a pair of diametrically-disposed rigidly-connected governor-arms

APRIL 5, 1902.

having operative connection with the ends of the governor-levers opposite the members, said governor-arms being provided with oppositely-disposed terminal fingers, and a guiding device mounted upon the disk to guide the movements of the governor-arms.

15. In a rotary engine, the combination with the cylinder, piston, shaft, valve and lifting abutment, of abutment-operating mechanism mounted on the cylinder, valve-opening mechanism supported above the cylinder, valve-closing mechanism disposed beyond the valve-opening mechanism and operatively connected therewith, a controlling-disk movable with the shaft and provided with a trip-block disposed to effect the actuation of the abutment-operating mechanism and the valve-opening mechanism in succession, and a centrifugally-operated governor-arm disposed to effect the subsequent actuation of the valve-closing mechanism in effect the automatic cut-off of the motive agent.

16. In a rotary engine, the combination with the cylinder, piston, engine-shaft and movable abutment, of a controlling-valve, a valve-opening arm connected thereto, a valve-closing arm, means connecting said arms to effect their movement in reverse directions, a disk movable with the engine-shaft, and relatively adjustable devices movable with the disk and disposed to operate the valve-opening arm and the valve-closing arm, in succession.

17. In a rotary engine, the combination with a plurality of cylinders, pistons, sliding abutments and an engine-shaft common to the several pistons, of a controlling-disk carried by said shaft, controlling-valves for said cylinders, abutment-operating arms disposed adjacent to the opposite side faces of the controlling-disk, valve-opening arms disposed adjacent to the opposite sides of the disk each of said blocks being disposed to effect the successive actuation of an abutment-operating arm and a valve-opening arm.

18. In a rotary engine, the combination with a plurality of cylinders, pistons, sliding abutments, and an engine-shaft common to the several pistons, of a controlling-disk carried by said shaft, controlling-valves for said cylinders, abutment-operating arms disposed adjacent to the opposite side faces of the controlling-disk, valve-opening arms disposed adjacent to the opposite sides of the disk, a pair of valve-closing arms operatively connected to the valve-opening arms, trip-blocks disposed at opposite sides of the disk and each disposed to effect the successive actuation of an abutment-operating arm and a valve-opening arm, and a centrifugally-operated governor-arm disposed at one side of the disk and arranged to operate the valve-closing arm.

19. In a rotary engine, the combination with the cylinder, piston, controlling-valves, valve-opening arms, an engine-shaft common to the several pistons, and a disk movable with the shaft, of governor members carried by the disk, governor-levers fulcrumed upon the disk and having connection with said members, and a plurality of governor-arms connected to said governor-levers and provided with laterally-disposed terminal fingers for engagement with the valve-opening arms.

20. In a rotary engine, the combination with the engine-cylinder, piston, controlling-valve, valve-opening arm, and the engine-shaft, of a disk movable with said shaft, a longitudinally-removable trip-block mounted on the disk to actuate the valve-opening arm, and a spring-bulb disposed at one end of said removable trip-block to maintain the shock incident to the contact of the block with the arm.

21. In a rotary engine, the combination with a plurality of cylinders and pistons, of a steam-chest, a plurality of controlling-valves located in the chest and each controlling the passage of the motive agent to a cylinder, means for automatically operating said valves in relation, a plurality of throttle-valves located in the steam-chest between the controlling-valves and cylinders, and operating mechanism connected to all of the throttle-valves for moving them in unison.

22. In a rotary engine, the combination with a cylinder, piston, shaft, valve and lifting abutment, of abutment-operating mechanism, valve-opening mechanism, valve-closing mechanism disposed beyond the valve-opening mechanism and operatively connected therewith, a controlling-disk operated by the engine and provided with a trip-block disposed to effect the actuation of the abutment operating mechanism and the valve-opening mechanism in succession, and governor mechanism disposed to effect the subsequent actuation of the valve-closing mechanism.

23. In a rotary engine, the combination with a plurality of cylinders, pistons, abutments, and a shaft, of a controlling-valve, a valve-opening arm connected therewith, a separate valve-closing arm, a block carried by the disk and disposed to operate the valve-opening arm, a governor-arm swung from the shaft and provided with a terminal finger disposed to operate the valve-closing arm, and a centrifugally-operated mechanism for positioning the governor-arm.

24. In a rotary engine, the combination with a plurality of cylinders, pistons, abutments, and a common shaft, of controlling-valves for the cylinders, valve-opening arms connected to the valves, valve-closing arms connected to the valve-opening arms, a controlling-disk operated by the

engine and provided at diametrically opposite points with blocks disposed to operate the valve-opening arms, rigidly-connected governor-arms loosely mounted on the shaft and extended therefrom in opposite directions, oppositely-extended fingers located at the outer extremities of the governor-arms and arranged to operate the valve-closing arms, and centrifugally-operated mechanism carried by the disk for positioning the governor-arms.

25. An engine-casing comprising two separate groups of cylinders, means disposed beyond the peripheries of the cylinders for effecting their rigid connection, securing-guns having their opposite ends extended into the opposed faces of the adjacent cylinders, and a covering-band arranged concentric with the cylinders and likewise extended into the opposed faces thereof.

696,618. COMBINED LIFTING AND TRACK-ALIGNING JACK.
PATENT J. M. WATSON, Savannah, Canada, assignor of one-half to John Duncan MacKenzie, Savannah, County and District of Algoma, Ontario, Canada. Filed July 26, 1901. Serial No. 70,016. (No model.)

Claim.—A jack of the class described comprising a dotted standard, a slidable bar provided with a claw and with a lifting-rod, a lever-socket fulcrumed on the standard and provided with a plate having a stud or boss, and a stud-pawl loosely mounted on the stud or boss and having an off-stand finger which is exposed at all times outside of the limits of the lever-socket, substantially as described.

696,614. MAILING-TUBE. THOMAS WHITLEY, SYRACUSE, N. Y.
Filed Apr. 24, 1901. Serial No. 57,204. (No model.)

Claim.—1. A mailing-tube partially divided or split lengthwise from one end for permitting said end to be expanded irrespective of the other end to facilitate removing of the contents of said tube, substantially as and for the purpose described.

2. A mailing-tube having one of its including walls split from one end through only a portion of its length to facilitate removing of the contents of said tube, substantially as and for the purpose set forth.

3. A mailing-tube split from one end through only part of its length and having a transverse slit leading from the lengthwise slit to facilitate removing of the contents of said tube, substantially as and for the purpose described.

4. A mailing-tube having one of its including walls split from one end through only a portion of its length and a flap covering the slit.

5. A mailing-tube slit lengthwise from one end through only part of its length, said slit terminating in a transverse slit of less length than the perimeter of the tube to facilitate removing of the contents of said tube, substantially as and for the purpose specified.

6. A mailing-tube having a lengthwise slit through only a portion of the length of one of its walls, and a fastening member adapted to be extended into the tube for holding the inclosed matter from outward displacement.

7. A mailing-tube having a lengthwise slit through only a portion of the length of one of its walls, a flap secured to the tube and covering the slit and a flexible member between the tube and flap for sliding said flap.

8. A mailing-tube having a lengthwise slit through only a portion of the length of one of its walls, a flap secured to the tube and covering the slit and a flexible member between the tube and flap for sliding said flap, said member being returned into the tube for holding the inclosed matter in position.

9. A mailing-tube slit lengthwise from one end, said slit terminating in a transverse slit of less length than the perimeter of the tube and a flap secured to the tube and covering the lengthwise slit.

10. A mailing-tube slit lengthwise from one end, said slit terminating

APRIL 1, 1902.

U. S. PATENT OFFICE.

89

ing in a transverse slit of less length than the perimeter of the tube, a flap secured to the tube and covering the lengthwise slit and a flexible member between the tube and flap for the purpose described.

696,615. VALVE. SYLVESTER WILSON, Clapnet, Mass. Filed May 21, 1901. Serial No. 61,285. (No model.)

Claim.—The combination with the steam-cylinder of a sawmill-engine; of twin valves comprising valve-casings respectively in communication with the opposite ends of the cylinder and each having an exhaust, a steam-supply pipe leading to both valve-casings, vertically-movable valves adapted to alternately open and close the steam ports and exhausts, and reversibly-disposed elbow-levers coupled together and connected with said valves to simultaneously admit steam to one end of the cylinder and exhaust from the opposite end, both valves being adapted to automatically and simultaneously shut off the supply of steam to the cylinder in case of breakage of the valve-operating connections.

696,616. PUMPING APPARATUS FOR WELLS. BENJAMIN WHEELER, HERRING, Ohio, assignor of one-half to Archibald C. Adams and James F. Herring, Herring, Ohio. Filed Apr. 11, 1901. Serial No. 55,282. (No model.)

Claim.—In a pumping apparatus for wells, the combination with the valve-piston having at its upper end a tubular coupling, a valve-cage

with parts connected to the coupling above the piston, a flanged tube clamped between the coupling and cage, a tubular collar rigidly connected to the lower end of the piston, a tube rigidly connected at its upper end to the collar, a cage connected to the lower end of the tube, a shoulder formed at the intersection of the tube and collar at the upper extremities thereof and a standing valve, of a rod connected at its lower end to the standing valve, its upper end having a cone-shaped head of a larger diameter than the opening in the collar connected to the upper end of the piston, said head coating with said opening of the collar, when an upward-and-downward stroke of the piston is made, said head also adapted to coast with said shoulder for the purpose of removing the standing valve from the well, substantially as specified.

696,617. CAR-TRUCK. EDWIN S. WOOD, Chicago, Ill. Filed July 27, 1901. Serial No. 60,576. (No model.)

Claim.—1. The combination with a pedestal car-truck and its axle-boxes, of crown-pieces attached to the side frame in a direct vertical plane above the axle-boxes, and rollers directly interposed between said crown-pieces and the top of the axle-boxes and adapted to afford independent lateral movement to such axle-boxes, substantially as set forth.

2. The combination with a pedestal car-truck and its axle-boxes, of crown-pieces attached to the side frame in a direct vertical plane above the axle-boxes, and rollers directly interposed between said crown-pieces and the top of the axle-boxes, the opposed bearing-surfaces for each roller having a curved or dish-like form adapted to afford lateral and self-centering movements to the axle-boxes, substantially as set forth.

3. The combination with a pedestal car-truck and its axle-boxes, of crown-pieces attached to the side frame in a direct vertical plane above the axle-boxes, and rollers directly interposed between said crown-pieces and the top of the axle-boxes, the opposed bearing-surfaces for each roller having a curved or dish-like form adapted to afford lateral and self-centering movements to the axle-boxes, and end flanges constituting stops, substantially as set forth.

4. The combination with a pedestal car-truck and its axle-boxes, of crown-pieces attached to the side frame in a direct vertical plane above the axle-boxes, and a series of rollers directly interposed between each crown-piece and axle-box and adapted to afford independent lateral movement to the axle-boxes, substantially as set forth.

5. The combination with a pedestal car-truck and its axle-boxes, of crown-pieces attached to the side frame in a direct vertical plane above the axle-boxes, and a series of rollers directly interposed between each crown-piece and axle-box, the opposed bearing-surfaces for each roller having a dish-like or curved form adapted to afford lateral and self-centering movements to the axle-boxes, substantially as set forth.

6. The combination with a pedestal car-truck and its axle-boxes, of crown-pieces attached to the side frame in a direct vertical plane above the axle-boxes, and a series of rollers directly interposed between each crown-piece and axle-box, the opposed bearing-surfaces for each roller having a dish-like or curved form adapted to afford lateral and self-centering movements to the axle-boxes, and end flanges constituting stops, substantially as set forth.

7. The combination with a pedestal car-truck and its axle-boxes, of crown-pieces attached to the side frame in a direct vertical plane above the axle-boxes, truck-plates secured to the tops of the axle-boxes, and rollers directly interposed between said crown-pieces and the truck-plates and adapted to afford independent lateral movement to the axle-boxes, substantially as set forth.

8. The combination with a pedestal car-truck and its axle-boxes, of crown-pieces attached to the side frame in a direct vertical plane above the axle-boxes, truck-plates secured to the tops of the axle-boxes, and rollers directly interposed between said crown-pieces and the truck-plates, the opposed bearing-surfaces for each roller having a curved or dish-like form adapted to afford lateral and self-centering movements to the axle-boxes, substantially as set forth.

9. The combination with a pedestal car-truck and its axle-boxes, of crown-pieces attached to the side frame in a direct vertical plane above

the axle-boxes, track-plates secured to the tops of the axle-boxes and rollers directly interposed between said crown-pieces and the track-plates, the opposed bearing-surfaces for each roller having a curved or dished form adapted to afford lateral and self-centering movements to the axle-boxes, and end flanges constituting stops, substantially as set forth.

10. The combination with a car-track and its axle-boxes of rollers interposed directly between the outer ends of the track-frame and the top of the axle-boxes, said rollers being subjected only to a crushing strain between the track-frame and axle-boxes, substantially as set forth.

696,618. COMBINED REIN-HOLDER AND STORM-APRON SUPPORTER. WILLIAM H. WOOLDRIDGE, Memphis, Tenn., assignor of one-half to Robert G. Butwick, Memphis, Tenn. Filed Oct. 18, 1901. Serial No. 79,394. (No model.)

Claim.—1. A device of the character specified, comprising a rigid member provided with suitable attaching means, a resilient rein-engaging member, and a combined stop and storm-apron supporter carried by the device.

2. A device of the character specified comprising resilient rein-engaging means, attaching means carried by the device, and storm-apron engaging means associated with the device and having a part to limit the insertion of the reins within the device.

3. A device of the character specified comprising a rigid member carrying a clip, a resilient rein-engaging member, and a combined stop and storm-apron supporter carried by the device.

4. A device of the character specified comprising a rigid member carrying a clip, a resilient rein-engaging member of a contour to clamp the reins against the rigid member, and a combined stop and storm-apron supporter carried by the lower portion of the device.

5. A device of the character specified, comprising a piece of metal bent upon itself to form a loop, one of the arms whereof constitutes a resilient rein-engaging member, and the other arm a means of attachment to a suitable support, and a combined stop and storm-apron supporter secured to the inner side of the bend, substantially as described.

696,619. WATCHMAN'S TIME-RECORDER AND SIGNAL. JAMES E. YEAZLE, Baltimore, Md. Filed Dec. 10, 1900. Serial No. 30,308. (No model.)

Claim.—1. The combination with a watchman's time-recording system having a series of signal-stations each provided with circuit-closing devices to be operated by the watchman on his rounds, and recording ap-

paratus having an operating or controlling magnet connected to the circuit of said devices, of a supervisory circuit containing signal-receiving apparatus, a signal-transmitter for said circuit, an electromagnet controlling the operation of the same, a circuit connecting said electromagnet with the watchman's signal-stations, and suitable switches at said stations adapted to connect the circuit-closing devices at said stations with the circuit of said electromagnet.

2. The combination in an electrical watchman's time-recorder system, of signal-stations connected with a suitable time-recorder over an electric circuit embracing the premises to be guarded, an electric switch at each station controlling the connection of the apparatus to be operated by the watchman on his rounds and arranged to be inaccessible to the watchman, an independent signal-circuit, supervisory signal-receiving apparatus connected therewith, a transmitter on said circuit, a controlling-circuit leading from said signal-transmitter to the signal-stations, and a switch at each station inaccessible to the watchman and operated to connect the apparatus operated by the watchman at said station with said controlling-circuit.

3. In a watchman's time-recorder and district or burglar alarm telegraph system, the combination of a series of signal-stations, a recording mechanism, an electrical circuit connecting each of said stations with said recording mechanism, an independent signal-recording mechanism, a signal-transmitter therefor, a controlling-circuit connecting the latter with each of the signal-stations, a circuit-closer at each station operated by the watchman, and a switch at each station inaccessible to the watchman and operated to connect said circuit-closer with the controlling-circuit of said signal-transmitter.

696,620. STORM-HOOD ATTACHMENT FOR LOCK. THOMAS H. YOUNG, Lincoln, Ill. Filed June 27, 1901. Serial No. 66,314. (No model.)

Claim.—1. A storm-hood for locks comprising a base-section, and a complementary cover-section having a slidable interlocking connection with the base-section and movable independently thereof.

2. A storm-hood for locks comprising a box-like base-section, and a complementary cover-section slidably supported upon the base-section and arranged to resume a closed position by gravitation.

3. In a storm-hood for locks, the combination with the lock-hoop, of a base-section having reversely-disposed holding-tongues engaging within the eye of the hoop at opposite points, and a slidable cover-section mounted upon the base-section.

4. In a storm-hood for locks, the same comprising a base-section having a staple-receiving eye and inclosing side walls provided with guiding-flanges, and a cover-section arranged over the open side of the base-section and having a top flange and side flanges overlapping the corresponding parts of the base-section, said cover-section also having interior grooved slide-lugs engaging the guiding-flanges of the base-section.

696,621. LIFE-BOAT. DR. CARL E. BAARDER, Bergen, Norway. Filed Mar. 18, 1901. Serial No. 61,314. (No model.)

Claim.—In combination, the curved hull, air-chambers beneath the thwart as well as in the upper part of the stem and stern, and a ballast-tank midship provided with stop-cock, rod and handle, said ballast-tank being in the bottom of the boat and controlled by said stop-cock, substantially as described.

696,622. WINDMILL. WILLIAM BAKER, Loyal, Wis. Filed June 17, 1901. Serial No. 64,224. (No model.)

Claim.—1. In a windmill, a wind-wheel having shiftable sails, crank-arms for the sails, a rotatable non-shiftable shaft for the wheel, an end-wise-shiftable trip-rod, and a detachable head carried by the rod and provided with recesses for the reception of the respective crank-arms, each recess having a transverse entrance-opening.

2. In a windmill, a non-shiftable rotatable hollow shaft, having a chambered hub, shiftable sails provided with journals rotatably mounted upon the hub and projected into the interior thereof, crank-arms carried by the outer ends of the journals, an end-wise-shiftable trip-rod mounted within the hollow shaft, a head carried by one end of the rod and provided with a marginal projected band which is located within the chambered hub, and also provided with bayonet-slots corresponding to and for the reception of the respective crank-arms, and means for imparting end-wise movement to the trip-rod and for shifting the sails.

3. In a windmill, a wind-wheel comprising a rim, a shaft having at one end a hub, the face of which is provided with bearings, sails having spokes journaled in the rim and in the bearings of the hub, and means for holding the wheel-spokes in the said bearings.

4. In a windmill, a wind-wheel comprising a rim, a shaft having at one end a hub, the face of which is provided with bearings, sails having spokes journaled in the rim and in the said bearings, and a sectional clamping-ring secured to the face of the hub and holding the wheel-spokes in the said bearings.

5. In a windmill, a wind-wheel comprising a rim, a shaft having at one end a hub the face of which is provided with bearings, sails having spokes journaled in the rim and in the bearings, a sectional clamping-ring secured to the face of the hub and holding the wheel-spokes in the said bearings, and stays secured to the rim and having their ends attached to the hub and to the shaft.

6. In a windmill, a wheel-supporting hollow shaft having a chambered hub, an end-wise-shiftable trip-rod, mounted therein and carrying at one end a hub, a rim supported from the head and the shaft, sails carrying spokes journaled in the rim and in bearings formed in the hub, crank-arms carried by the spokes and projecting into the chamber of the hub, a head carried by the head and having recesses to be engaged by the crank-arms, the inner end of the head being adapted to engage with the vertical wall of the hub, and means connected with the trip-rod to keep the head in engagement with the said wall, whereby to hold the sails out of gear.

696,623. CULTIVATOR. JOHN T. BROWN, Canton, Ohio. Filed Sept. 4, 1900. Serial No. 24,940. (No model.)

Claim.—1. In a cultivator the combination of a center bar, a head connected thereto, hinged bars connected to the head located upon the center bar, handle-supports fixed to the hinged bars, a right and left screw-threaded shaft journaled to the handle-supporting bars, right and left hand screw-threaded eyes located upon the screw-threaded shaft, and arms connected to the eyes and to the hinged bars and handles carried by the handle-supports, substantially as and for the purpose specified.

2. The combination of a cultivator-frame consisting of two hinged bars and a center bar, a left and right handed screw-threaded shaft located between the cultivator-handles, handle-supports having connected thereto, a rod, arms provided with right and left hand screw-threaded eyes, said arms provided with staples to engage the rod connected to the handle-supports, substantially as and for the purpose specified.

696,624. ECCENTRIC-CHAIN LIFT-PUMP. WILLIAM C. BONE, Peterborough, Canada. Filed June 7, 1901. Serial No. 65,502. (No model.)

Claim.—1. In a pump, the combination with a plunger-rod and a suitable framework, of a power-wheel provided with a slotted web, plates fastened adjustably to the slotted web, a fulcrum-bolt extending through the slotted web and the plates and supported in the framework, and a chain attached to the power-wheel and connected to the plunger, substantially as described.

2. In a pump, the combination with a plunger-rod and a suitable framework, of a power-wheel having a slotted web, plates applied to opposite sides of the web and connected by bolts which pass through certain slots in the web, a fulcrum-bolt passing through the plates and another slot in the web of the power-wheel and attached to the framework, and a chain attached to the power-wheel and connected to the plunger-rod, substantially as described.

3. In a pump, the combination with a plunger-rod and a suitable framework, of a power-wheel having a diametrical web provided with the central and side slots, plates applied to opposite sides of the web to open the slots therein, the bolts passing through the side slots in the web and fastening the plates adjustably to the power-wheel, a fulcrum-bolt passing through the plates and the central slot in the web of the power-wheel and attached to the framework, and a chain attached to the power-wheel and connected to the plunger-rod, substantially as described.

4. In a pump, the combination with a plunger-rod, of a power-wheel, a chain attached to the power-wheel and to the plunger-rod, a yieldable link adjustably supported on the plunger-rod above the point of attachment of said chain thereto, a cushion-spring operatively connected to the yieldable link, and a second chain attached to the yieldable link and to the power-wheel, substantially as described.

5. In a pump, the combination with a power-wheel, a plunger, of a chain connected to the power wheel and the plunger, a spring-actuated link supported by the plunger-rod, and another chain connected to the link and the power-wheel, substantially as described.

696,625. IRONING-TABLE. EDWARD E. CROWLEY, Columbia, Ohio. Filed Sept. 12, 1901. Serial No. 75,128. (No model.)

Claim.—In an ironing-table, the combination with a table top or board 1 and a forward support therefor, of a rear support comprising a transverse bar hinged directly to said table-top and legs projecting from said bar, a guide-frame on the under side of the board in rear of said bar 2, a sliding iron-supporting block 14 having arms 13 movably supported

in said guide-flange, said arm adapted to extend beneath the bar 2, and lock said bar against swinging on its hinges, substantially as specified.

696,626. GARMENT-CLASP. JAMES COHEN, Brooklyn, N. Y., assignor to The City Button Works, New York, N. Y., a Corporation of New York. Filed Jan. 14, 1902. Serial No. 59,703. (No model.)

Claim.—1. A garment-clasp comprising a rubber disk thickest at its periphery and gradually tapering toward the center and cross-cut at the central portion whereby resilient lips are provided, a metal holder secured to the periphery of said disk, and a button rising from any suitable base, said metal holder and base being attached to suitable webbing, substantially as set forth.

2. In a garment-clasp, the combination of the open-faced metal holder having a slotted extension, the rubber disk secured at its periphery within the face of said holder, said disk being thickest at its periphery and gradually tapering toward the center and cross-cut at its center whereby resilient lips are afforded, and a slotted base having a button rising therefrom, said holder and base being attached to suitable webbing through their respective slots, substantially as set forth.

696,627. CAR-TRUCK. HARVEY A. CURTIS, Chicago, Ill. Filed June 5, 1901. Serial No. 53,343. (No model.)

Claim.—1. An equalizer-bar for car-trucks made of cast-steel, and comprising the following elements: a straight horizontal intermediate body portion, a pair of pedestals at the opposite ends thereof, respectively, a pair of parallel longitudinal bearing-plates on top of each pedestal, and a series of cone-shaped hollow tops or caps curving to unite said bearing-plates laterally with the tops of the pedestals, all of said parts being cast integral and of uniform thickness throughout, substantially as described.

2. An equalizer-bar for car-trucks made of cast-steel, and comprising the following elements: a straight horizontal intermediate body portion of I-beam section throughout, a pair of pedestals at the opposite ends thereof, respectively, a pair of parallel longitudinal bearing-plates on top of each pedestal, and a series of cone-shaped hollow tops or caps curving to unite said bearing-plates laterally with the tops of the pedestals, said tops or caps having depending annular flanges adapted to rest in the upper ends of the springs, all of said parts being cast integral and of uniform thickness throughout, substantially as described.

3. In a car-truck, the combination with a journal-box having laterally-extending lugs on either side of the base portion thereof and forming seats for springs, of a pedestal straddling the same and having corresponding seats for the springs in its upper portion, and springs vertically seated between and engaging the seats of the journal-box and of the pedestal, respectively, substantially as described.

4. The combination with the equalizer-bar having pedestals cast integral therewith, each pedestal having seats for the equalizer-springs on each side of the top portion thereof, of journal-boxes lying within the pedestals, each journal-box having horizontally-extending integral lugs on either side of the base portion thereof and forming seats for the springs, and vertically-arranged springs disposed between and at their opposite ends engaging the aforesaid seats of the pedestal and journal-box respectively, substantially as described.

5. In a car-truck, the combination with an equalizer-bar having a horizontal intermediate portion, and a pedestal rising integrally therefrom at each end thereof, each pedestal having a pair of seats for the upper ends of the equalizer-springs on each side of the central vertical longitudinal plane thereof, the seats of each pair being disposed on opposite sides of the central vertical transverse plane of the pedestal, of a journal-box slidably engaging each pedestal, said journal-box having a pair of laterally-extending lugs on each side thereof, said lugs forming seats for the lower ends of the equalizer-springs, and the lugs of each pair being disposed in vertical alignment with the corresponding seats of the equalizer-bar themselves; and permitting the vertical play of the side members of the pedestal therebetween, springs interposed between the seats of the pedestal and of the journal respectively, and a soft-wood wheel-piece rigidly connecting the tops of the pedestals, substantially as described.

696,628. REGENERATING-MACHINE. ARTHUR A. BROWN, Toronto, Canada. Filed May 4, 1902. Serial No. 718,046. (No model.)

Claim.—The combination, in a distorting-machine, of a rotating cylinder, having a series of beater or breaker pivoted thereto, a hopper, a curved concave grate or screen cut concentrically to the cylinder to form a throat contracting in the direction of the progress and elimination of the material as it is reduced, and a hood or casing extending over the beater to a point on the same side as the feed.

696,629. MACHINE FOR MAKING BUTTONS. MAX GARDNER, Philadelphia, Pa., assignor to Abraham Garbel and Max Garbel, Philadelphia, Pa., copartners trading as Garbel Bros. Co. Filed Nov. 18, 1901. Serial No. 55,055. (No model.)

Claim.—1. In a button-making machine, the combination with a tool and support therefor, of a chuck-bearing frame, a series of chucks therein, means for intermittently rotating said frame to advance the chucks successively in proximity to the tool, pulleys on said chucks, a driven pulley below the same, a band passing about the latter pulley and the chuck-pulleys, a movable support for said driven pulley, said support being automatically maintained in the band tension about the pulleys, and means for actuating said driven pulley.

2. In a button-making machine, the combination with a tool and support therefor, of a chuck-bearing frame, a series of chucks therein, and means for intermittently rotating said frame to advance the chucks successively in proximity to the tool, pulleys on said chucks, a driven pulley below the same, a belt passing about the latter pulley and the chuck-pulleys, a main shaft, a web-frame chock thereon for the support of the

shaft of the driven pulley, and gearing between the main shaft and the pulley-shaft.

3. In a button-making machine, the combination with a tool and support therefor, of a shaft, a chuck-bearing frame thereon, a series of rotatable chucks in said frame, normally closed chucks in said chucks, means for intermittently rotating said frame, and means for successively opening the chucks during the movement of said frame, the last-named means including longitudinally-movable spindles arranged within said chucks and connected with the chucks, and a stationary cam mounted in the path of said spindles and adapted to be engaged thereby during the rotation of the chuck-bearing frame.

4. In a button-making machine, a chuck comprising a sleeve or casing, a series of clamping-jaws therein having beveled surfaces, a beveled annulus coaxial with each surface, an axial spindle extending between said jaws and connected with the annulus, and a spring tending to retract said annulus and maintain the jaws in closed or clamping position.

5. In a button-making machine, a chuck-bearing frame, means for intermittently rotating the same, and a series of externally-beveled clamping-jaws in said sleeve or casing, a beveled annulus coaxial with the beveled portions of the jaws, an axial spindle extending through said sleeve or casing and between the jaws, a connection between said spindle and the annulus, and a spring tending to retract said spindle and annulus and thereby to maintain the jaws in closed or clamping position, in combination with a cam mounted in the path of the respective spindles and adapted to be engaged thereby during the rotation of the chuck-bearing frame.

6. In a button-making machine, the combination with a tool and tool-support, of a shaft, a chuck-bearing frame thereon, a series of chucks in said frame, a spiral gear on said shaft provided with intervals with transverse interstitial spaces, a coaxial gear provided with a series of teeth and a peripheral rim, as described, and means for rotating the latter gear.

696,680. COMBINED VALVE AND SWITCH APPARATUS. ROBERT C. GARLAND, Chelsea, Mass., assignor of one-half to W. A. Stevens, East Boston, Mass. Filed Nov. 22, 1901. Serial No. 59,305. (No model.)

Claim.—1. The combination with a motor and an electric generator operated thereby, of a battery, a combined valve and switch apparatus comprising a valve, a switch-arm movable with the valve, and two contact-pieces located in the path of the switch-arm, and connected respec-

tively with the two sources of electricity specified, whereby the switch-arm may complete either circuit.

2. The combination with a motor and an electric generator operated thereby, of a battery, a combined valve and switch apparatus comprising a valve, a switch-arm movable with the valve, a battery contact-piece arranged in the path of the switch-arm to make contact therewith when the valve is in one position, and a dynamic contact-piece arranged in the path of the switch-arm to make contact therewith when the valve is in another position, the switch-arm being out of contact with the contact-pieces when the valve is in a third position.

3. The combination with a motor and an electric generator operated thereby, of a battery, a valve-casing, two contacts supported by and insulated from the casing and also insulated from each other, a valve movable in said casing and a switch-arm affixed to the valve, the said contacts being located in the path of the switch-arm and connected respectively with the two sources of electricity specified, whereby the switch-arm may complete either circuit.

4. The combination with a motor and an electric generator operated thereby, of a battery, a valve-casing having two standards, insulating-blocks affixed to said standards, contact-pieces affixed to said blocks and insulated thereby from the standards and from each other, a rotary valve in said casing adapted to occupy one of two positions when open, and a switch-arm affixed to said valve and adapted to make contact with one contact-piece or the other when the valve is in an open position, the said contact-pieces being arranged so that the arm is out of contact with both of them when the valve is closed.

696,681. REFRIGERANT-RECEPTACLE AND BOUTONNIERE. JOHN A. SMITH, Brooklyn, N. Y. Filed July 23, 1901. Serial No. 60,205. (No model.)

Claim.—1. In combination with an artificial flower carrying a piece of tubing and a boutonniere the stem of which is detachably inserted in said tubing, a cup or receptacle, a stem composed of a plurality of wires, the said cup or receptacle being grasped by the said wires, substantially as described.

2. In a device of the character described, a cup or receptacle, a stem composed of a plurality of wires, the ends of said wires adapted to grasp said cup or receptacle, a piece of tubing carried by said stem, and a boutonniere detachably secured in said tubing and extending beyond the said cup or receptacle, substantially as described.

3. In combination with an artificial flower, a cup or receptacle, a stem composed of a plurality of strands or lengths of wire, the ends of said strands being bent to form fingers adapted to grasp said cup or receptacle, substantially as described.

696,682. PHOTOGRAPHIC FABRIC AND PROCESS OF PREPARING SAME. FREDERICK H. C. GARDNER, New York, N. Y., assignor to Greater Art Company, a Corporation of West Virginia. Filed Apr. 29, 1901. Serial No. 54,086. (No specimens.)

Claim.—1. The process of preparing fabric for photographic use, by applying to the fabric a solution containing the aqueous extract of the white algae and subsequently sensitizing, and drying the fabric.

2. The process of preparing fabric for photographic use, by mixing extract of white algae, citric acid, and ammonium chloride, then wetting the fabric with the solution, then drying it, then applying a sensitizing solution, and finally again drying it.

3. A prepared sensitized fabric for photographic processes, characterized by its being impregnated with white-algae extract and by the presence of a sensitizing substance.

4. A prepared fabric for photographic processes, characterized by the presence of the dried product separated from a mixture of extract of white algae *Chlorella crispus*, citric acid, and ammonium chloride.

696,683. INVERSE-IMPRESSION PRINTING. EDWARD W. HALL, Rutherford, N. J., assignor to himself, and E. Charles Fisher and John L. Gentry, New York, N. Y. Filed Feb. 12, 1902. Serial No. 54,792. (No model.)

Claim.—1. An improvement in the art of printing or developing pictures or other representations, the herein-described method consisting in producing upon an impression-receiving surface a visible pictorial or other representation constituting in itself an entity or individual whole and also a substantially invisible pictorial or other representation constituting in itself an entity or individual whole, said visible and invisible representations being arbitrarily distinctive with respect to each other and respectively associated or correlated so that they are adapted to conjointly produce a complete pictorial or representative entity or whole in which the visible association of the visible and invisible parts completes the full motive or theme of the pictorial or other representation, and then developing the invisible representation to render the same visible in association with the visible representation to produce said composite complete entity or whole.

2. An impression-receiving sheet having upon its surface a visible pictorial or other representation constituting in itself an entity or individual whole and also having a substantially invisible pictorial or other representation constituting in itself an entity or individual whole, said visible and invisible representations being arbitrarily distinctive with respect to each other and respectively associated or correlated so that they are adapted to conjointly produce a complete pictorial or representative entity or whole in which the visible association of the visible and invisible parts complete the full motive or theme of the pictorial or other representation, said invisible impression being capable of development to produce visibility.

3. An impression-receiving sheet having visibly printed or produced upon its surface a pictorial or other representation constituting in itself an entity or individual whole and also having a pictorial or other representation constituting in itself an entity or individual whole and printed or produced upon its surface in a substantially invisible or sympathetic ink capable of development to visibility by treatment of the surface having said invisible representation with a pencil, crayon, or other material or substance which will be "taken up" by said ink, said visible and invisible representations being arbitrarily distinctive with respect to each other and respectively associated or correlated so that they are adapted to conjointly produce a complete pictorial or representative entity or whole in which the visible association of the visible and invisible parts complete the full motive or theme of the pictorial or other representation.

696,684. CHUCK. JAMES HARRISON, Springfield, Vt. Filed Mar. 20, 1901. Serial No. 25,081. (No model.)

Claim.—1. A chuck having jaws, means for closing said jaws and supports co-operating with said jaws for holding said jaws open when the chuck is open, said supports frictionally engaging said jaws at their sides, whereby said jaws are movable relatively thereto.

2. A chuck having radial jaws and wedge-shaped radially-movable spacers interposed between said jaws.

3. A chuck having radial jaws and spring-tensioned spacers having provisions for holding said jaws open.

4. A chuck having radial jaws, wedge-shaped spacers between said jaws, and means whereby when the jaws are moved toward their common center, the spacers move away from said center, and vice versa.

5. A chuck having wedge-shaped jaws, and radially-movable wedge-shaped spacers interposed therewith.

6. A chuck having wedge-shaped jaws and spring-tensioned wedge-shaped spacers.

7. A chuck having radial jaws, radial spacers between said jaws, said jaws and spacers being grooved, and a sleeve having an internal flange extending into said grooves, and thereby holding the spacers against movement longitudinally of the chuck relatively to the jaws.

8. A chuck having an annular abutment, jaws located within said abutment, and independent radially-movable spacers located between said jaws for holding them against said abutment, when said jaws are open.

9. A chuck having jaws radially disposed and tapering from their outer to their inner ends, and spacers interposed between the sides of the jaws and movable relatively to said jaws for the purpose described.

10. A chuck having jaws, means for opening and closing said jaws, and supplemental means for closing said jaws with a spring-pressure against the work.

11. A chuck having jaw-operating means, and also having provisions for closing said jaws upon the work prior to the actuation of said jaws by said operating means.

12. A chuck having jaws, means for opening and closing said jaws, and provisions whereby said jaws are closed yieldingly against the work, prior to the operation of the jaw-closing means.

13. A chuck having jaws, a sliding sleeve for positively closing said jaws, adapted to be operated manually or automatically, and a spring for closing said jaws prior to the actuation of said jaws by said sleeve.

14. A chuck having jaws, a spring for bringing the jaws against the work, and means additional thereto for tightly wedging the jaws against the work after the operation of the spring.

15. A chuck having jaws, a sleeve for actuating the jaws, means for actuating said sleeve, and mechanism between said means and said sleeve for automatically moving said sleeve to the other when said means is actuated.

16. A chuck having jaws, a jaw-closing sleeve, an outer collar for moving said sleeve, and means between said collar and sleeve for automatically moving one relatively to the other.

17. A chuck having jaws, a jaw-actuating sleeve, a collar thereon to move said sleeve, a nut threaded on said sleeve, means for automatically rotating said nut in one direction or the other, when the collar is moved.

18. A chuck having jaws, means for positively locking said jaws against the work, and supplemental provisions for engaging said jaws with the work prior to the locking of said jaws.

19. A chuck comprising a rotary spindle, a stationary friction member, jaws, a sleeve for operating said jaws and having a friction member complementary to the first-mentioned friction member whereby when said members are engaged the said sleeve is moved to actuate the jaws, and means for causing the engagement or disengagement of said friction member.

20. A chuck for bar-working machines, comprising a hollow spindle by which it may be rotated, and through which the bar may be passed from the rear of the jaws for engaging the jaws, means for operating the jaws, and means independent of and in the rear of the jaws for centering the work relatively to the jaws.

21. A chuck having a hollow spindle for the reception of work passed longitudinally therethrough, jaws on said spindle, means for operating said jaws, and a beveled centering-bushing independent of said jaws located within said spindle in the rear of said jaws.

696,685. MEANS FOR REDUCING CONDENSATION OF STEAM IN CYLINDERS. GEORGE E. HARVEY, Pittsburgh, Pa. Filed June 22, 1901. Serial No. 25,082. (No model.)

Claim.—1. In a device of the character described, a steam-cylinder, a piston in the cylinder, a cylindrical jacket inclosing the cylinder and provided with a conical top extending above and over the cylinder, a live-steam pipe opening into the bottom of the cylinder, an exhaust-steam pipe leading from the steam-pipe to take steam from the cylinder below the piston and opening into the space between the jacket and the cylinder, a valve operatively interposed in the exhaust-steam pipe, and an outlet-pipe opening from the jacket opposite to the inlet end of the exhaust-steam pipe.

2. In a device of the character described, a steam-cylinder, a piston in the cylinder, a cylindrical casing surrounding the cylinder and provided with a conical top extending above and over the cylinder, a steam-pipe opening into the bottom of the cylinder to conduct live steam therein, an exhaust-steam pipe leading from the live-steam pipe adjacent to its entrance into the cylinder to take steam from the cylinder from below the piston and conduct it into the space between the jacket and the cylinder, a valve in the exhaust-steam pipe to control the passage of steam there-through, and a branch pipe 10 extending from the live-steam pipe to a feed-water heater, substantially as described.

696,686. SPLIT-PULLEY ATTACHMENT. ALBERT W. KIMM, Ballard, Wash., assignor of one-half to Eben E. Kimm, Seattle, Wash. Filed June 4, 1901. Serial No. 25,083. (No model.)

Claim.—In a split pulley, the combination with the pulley-section, the shaft, and U-bolts holding the sections on the shaft, of a segmental bar fitted to each U-bolt and the shaft to secure the U-bolts and shaft together, said segmental bar having at each end oppositely-disposed sharp edges engaging respectively with the shaft and U-bolts, the intermediate portions of the bar being respectively free from engagement with the U-bolts and shaft, for the purpose specified.

696,687. AUTOMATICALLY-CLOSED LINETYPE MOLD-BLOCK. CHARLES HALLIWELL, Broadmonth, England, assignor to the Hargreaves Linotype Company, New York, N. Y. Filed Sept. 20, 1901. Serial No. 25,084. (No model.)

Claim.—1. In a linetype-casting machine the combination with the fixed frame and mold-wheel, and means in operative connection with the mold-wheel imparting to it intermittent partial rotation and reciprocal axial movement, of a mold-block secured to the mold-wheel, a mold-die and guide in the mold-block, a core in the guide movable into and out of the mold-die, projections on the core and co-operating cams on the core projections, and on the fixed frame in the rectilinear path of said projections, for projecting the core into, and retracting it from, the mold-die substantially as set forth.

2. In a linetype-casting machine the combination with the mold-wheel and a mold-block thereon slotted to form respectively part of the casting-mold and a guide, of a core in the guide movable into and out of

the mold-die transversely and co-operating cams on the core and fixed frame for projecting the core into, and retracting it from the mold-die substantially as set forth.

3. In a linetype-casting machine the combination with the mold-wheel and means operatively connected therewith alternately moving it rotatively and axially, and a mold-block, on said wheel slotted to form respectively part of the casting-mold and a guide, of a core in the guide, movable into and out of the mold-die transversely, a bar on the core and fixed device adapted to engage the bar when the mold-wheel is moved axially for projecting the core into, and retracting it from, the mold-die substantially as set forth.

4. In a linetype-casting machine the combination with the mold-wheel and means operatively connected therewith alternately imparting partial rotation in the same direction and reciprocal axial motion, and a mold-block on said wheel slotted to form respectively part of the casting-mold and a guide, of a core in the guide, movable into and out of the mold-die transversely, a bar on the core, cam projections on the bar and cam projections on the fixed machine-frame adapted to engage respectively the bar and the cam projections on the bar when the mold-wheel is moved axially forward substantially as set forth.

5. A mold for a linetype-machine, consisting of a rigid body having parallel front and rear faces, a slot therethrough in which to cast the linetype, and a transverse dovetail groove in the rear face, in combination with a sliding core mounted in said slot and having its rear face flush with that of the mold, whereby the mold is adapted to support and carry the core, and the core adapted to form a recess in the base of the slug to release the slug, this it may be quoted.

6. In a linetype-machine, a rigid mold having parallel front and rear faces, a slot in which the linetype is formed, and a transverse groove in its rear face, in combination with a sliding core mounted in said groove and sustained by the mold flush with its surface and with automatic mechanism for advancing the core across the mold-die and retracting it therefrom.

696,688. AUTOMATIC FUEL-REGULATOR. HENRY A. ROUSE, Jr., Hampstead, England. Filed May 22, 1901. Serial No. 25,085. (No model.)

Claim.—In an automatic regulator the combination of a valve-casing provided with an inlet and an outlet, a valve adapted to close said outlet when moved in either direction and to permit a maximum flow in an intermediate position, one of said parts being provided with a constantly open aperture, a diaphragm adapted to be actuated by pressure and connection between said diaphragm and said valve.

696,689. AUTOMATIC VARIABLE-EXHAUST APPARATUS. HENRY E. HUFF, Boston, Mass., assignor of two-thirds to Arthur D. Curtis and Smith P. Burton, Jr., Boston, Mass. Filed June 22, 1901. Serial No. 25,086. (No model.)

Claim.—1. The combination with the cylinder, exhaust-passage, and connections between said cylinder and the exhaust-passage of a valve adapted to automatically open and close the communication

tion between the exhaust-passages and the reservoir, and means for manually operating said valve.

2. The combination with the cylinder, exhaust-passages, and the pipes connecting the exhaust-passages with the reservoir, of a valve-casing having a cylindrical extension adapted to contain a piston, a valve in said valve-casing, and connections between said valve and piston whereby the valve may be opened.

3. The combination with the boiler and reservoir, the pipes connecting the reservoir with the exhaust-passages and exhaust-conduit, a valve-casing having a cylindrical extension, a piston in said extension, a valve adapted to control communication between the reservoir and exhaust-passages and connected with said piston, and means for the admission of steam from the boiler to the cylindrical extension of the valve-casing whereby the valve may be opened, as set forth.

4. The combination with the boiler, the valve-casing, the valve, the piston, the stem, connecting the valve and piston of a valve, adapted to open and admit steam from the boiler to the piston at a predetermined pressure of the steam in the boiler and to close when said pressure is reduced, connections, as the pipe, between the valve and the cylindrical extension, means for permitting the escape of steam from the cylinder after the piston has been raised, and means for regulating the pressure of steam upon the piston, as set forth.

696,640. GAS-LAMP. ALFRED E. HURFERT, Kalamazoo, Mich. Filed Jan. 6, 1902. Serial No. 22,604. (No model.)

Claim.—1. In a lamp, the combination of a central supply-pipe; lateral arms thereon carrying burners; a main gas-valve in the central supply pipe or passage to control the flow of gas to the said burners; a cross-arm on said valve with suitable disk stops positioned to strike one of said lateral arms; chains *a, a'* connected to each end of said cross-arm; a pilot-valve connected above said main gas-valve; a tube extending upwardly therefrom containing small jet-perforations; a valve with stop there-

on to hold the same a little off from its seat to permit a small flow of gas; a spring *s'* to hold the said valve normally toward its closed position; a lever with connection adapted to act against said spring consisting of chain *a'* and spring *B* being of greater strength than the valve-spring; and the chain *a'* being connected by a loop to the chain *a'*, all coacting substantially as described and for the purpose specified.

2. In a lamp, the combination of a central supply-pipe; lateral arms thereon, carrying burners; a main gas-valve in the central supply pipe or passage to control the flow of gas to the said burners; a cross-arm on said valve with suitable stops; chains *a, a'*, connected to each end of said cross-arm; a pilot-valve connected above said main gas-valve; a tube extending upwardly therefrom containing small jet-perforations; a valve with a stop thereon to hold the same a little off from its seat to permit a small flow of gas; a spring *s'* to hold the said valve normally toward its closed position; a lever with connection adapted to act against said spring, consisting of chain *a'* and spring *B* connected to the said lever, the said spring *B* being of greater strength than the valve-spring; and the chain *a'* being connected by a loop to the chain *a'*; all coacting substantially as described and for the purpose specified.

3. In a lamp, the combination of a main supply-pipe; burners connected thereto with a valve for controlling the supply of gas; stops for said valve for both its open and closed positions; and a pair of chains connected to control said valve; a pilot-light with an independent connection to the gas-supply; a pilot-light valve in such connection with a stop to hold it a little open to permit a small flow of gas; a spring, or other means, for holding the same automatically in this position; a connection to said pilot-valve containing a spring of sufficient strength to overcome the resistance of the valve and open the same, the main burner-chain or opening connection being connected thereto, whereby in operation, a pull on the pilot-light connection will first open the pilot-light valve wide and then open the main gas-valve, and when released, will permit the pilot-light to close automatically, for the purpose specified.

4. In a gas-lamp, the combination of a burner with a gas-valve in the main supply; a pilot-light independently connected; a valve for the pilot-light with a stop to hold it slightly open; a spring to throw the valve against the stop; a connection containing a spring of greater strength than the pilot-light-valve spring, the same being coupled with the connection to the main gas-valve, whereby the pilot-light will be open to the full extent and the burner-valve then opened and the pilot-light will close when the tension is released, for the purpose specified.

696,641. CAR-TRUCK. WILLIAM M. JOHN, Dayton, Ohio. Filed Jan. 4, 1902. Serial No. 22,554. (No model.)

Claim.—1. In a truck, the combination with a bolster, of a truck side frame consisting of one integral piece, the vertical members of which have openings therein, and bolster-guides projected through said openings and engaging with the ends of said bolster to secure the same to said frames.

2. In a truck, the combination with a bolster, of a truck side frame consisting of one integral piece, bolster-guides entering openings in the vertical portions of said truck side frame and serving to engage the ends of the bolster, and means for covering said bolster-guides to said frame.

3. In a truck, the combination with a bolster, of truck side frames each of which consists of one integral piece, the vertical members of which have openings therein, combined bolster-guide and brake-beam hangers

attachable in said openings and by means of which the ends of the bolster and the ends of the brake-beam are supported in said side frames.

4. In a truck, the combination with a bolster having vertical grooves in the ends thereof, of integral truck side frames, bolster-guides projecting into openings in the vertical portions of said truck-frames and entering the grooves in the ends of the bolster, substantially as specified.

5. In a truck, the combination with a bolster, of integral truck side frames, the same consisting of upper and lower portions which are joined by vertical portions and which terminate in end portions which are co-actable to the journal-bones, combined bolster-guides and brake-beam hangers secured to the vertical portions of said frames and serving to hold the ends of the bolster in engagement with the frames and to support the brake-beam, substantially as specified.

6. In a truck, the combination with a bolster, of integral side frames, the upper and lower members of which are joined by integral vertical members, bolster-guides attachable to said vertical members and by means of which connections are made between the side frames and the ends of the bolster, a combined spring-rod and truck-frame brace connecting the lower portions of said side frames and providing a seat for the spring.

7. In a truck, the combination with a bolster and truck-springs, of integral truck side frames, combined bolster-guides and brake-beam hangers attachable to the vertical members of said side frames, and by means of which the ends of the bolster are secured to the upper portions of said side frames, a combined spring-rod and truck-frame brace connecting the lower portions of the side frames and providing seats for the springs.

8. In a truck, the combination with a bolster and brake-beam, of integral side frames, combined bolster-guides and brake-beam hangers attachable to the vertical members of said side frames and by means of which the ends of the bolster are secured to said side frames, and the brake-beam is suspended from said side frames.

9. In a truck, the combination with a bolster having vertical channels or grooves in the sides of the ends thereof, of integral truck side frames, the said frames having vertical portions connecting the upper and lower parts of said frames, the ends of the bolster being projected into the space between said vertical portions, bolster-guides secured to said vertical portions of the truck side frames, and the inner ends of said bolster-guides being projected into the channels or grooves in the ends of the bolster, whereby a connection is made between the bolster and said truck side frames.

10. In a truck, the combination of a bolster having channels or grooves in the sides of the ends thereof, helical springs, integral truck side frames, bolster-guides secured to said truck-frames with their ends projected into the channels or grooves in the ends of the bolster, and a combined spring-rod and truck-frame brace connecting the lower portions of said frames and providing seats for the springs.

11. In a truck, the combination of a bolster, a combined spring-rod and truck-frame brace, springs inclined between the ends of said bolster and said spring-rod and truck-frame brace, integral truck side frames, bolster-guides attachable to the vertical members of said side frames and by means of which the bolster is secured to the upper portions of said side frames, and means for securing the ends of the combined spring-rod and truck-frame brace to the lower portions of the side frames.

12. In a truck, the combination with a bolster, of integral truck side frames, the said truck side frames having vertical portions which join the upper and lower parts of said frames and between which the ends of the bolster project, the said vertical parts of the truck side frames having openings or slots therein, combined bolster-guides and brake-beam hangers, said bolster-guides having portions which are projected through the openings or slots in the vertical parts of the truck side frames and engage with the opposite sides of the ends of the bolster, and links connecting the brake-beam with said combined bolster-guides and brake-beam hangers.

696,642. MECHANISM FOR TRANSMITTING POWER FROM VEHICLE GROUND-WHEELS. CLARENCE L. V. KIRBY, Newark, Ohio, assignor to the Newark Machine Company, Newark, Ohio, a Corporation of Ohio. Filed Dec. 7, 1901. Serial No. 84,968. (No model.)

Claim.—1. In a mechanism for transmitting power from vehicle wheels, the combination with a journaled axle 6, a ground-wheel rotatably mounted thereon, said ground-wheel having a cup-like inward projection and spring-actuated pawls pivoted within said cup projection, of a ratchet-wheel keyed on said axle and adapted to be received by said cup projection and to be engaged by said pawls and a power-wheel 12, carried by said axle, substantially as specified.

2. In a mechanism for transmitting power from vehicle ground-wheels, the combination with the journaled axle 6, a ground-wheel rotatably mounted thereon, said ground-wheel having a cup-like inward projection 3 and spring-actuated pawls within said cup projection, of a ratchet-wheel carried on said axle 6, said ratchet-wheel adapted to be received by said cup projection and having formed on its face and on opposite sides of its central opening curved guide-lugs 12 each leading to a tooth-notch of said wheel, and a power-wheel 13 carried on said axle 6, substantially as specified.

696,643. END-GATE FOR MANURE SPREADER OR SIMILAR BEDS. CLARENCE L. V. KIRBY, Newark, Ohio, assignor to the Newark Machine Company, Newark, Ohio, a Corporation of Ohio. Filed Dec. 7, 1901. Serial No. 84,969. (No model.)

Claim.—1. In an end-gate for manure-spreader or similar beds, the combination with the bed-body 1, of bracket-arms rising from the rear end thereof and a semirotatable shaft extending between said bracket-arms, of an end-gate body and its supporting-frame, said body adapted to fit between the sides of said bed, bars 6 jointly connecting said brackets and said end-gate frame and means connected with said shaft for imparting a semirotary motion thereto, substantially as specified.

2. In an end-gate for manure-spreader or similar beds, the combination with the bed-body 1, of angular bracket-arms rising from said bed sides and a semirotatable shaft extending between said brackets, of an end-gate body adapted to fit between the sides of said bed, bars 6 jointly connecting said brackets and end-gate frame and bars 11 having their forward ends pivotally connected with said end-gate frame and their rear ends rigidly connected with said shaft and means for imparting a semirotary motion to the shaft, substantially as specified.

3. In an end-gate for manure-spreader or similar beds, the combination with a bed, brackets 3 rising from the rear end thereof, an end-gate body adapted to enter said bed as described, and swinging frame-bars connecting said end-gate frame within said shaft and brackets, of a telescoped lever at the forward end portion of the bed, a spring connecting the lower end of said lever with a fixed point in front of the latter and a rod 15 having its ends pivotally connected with an operating-arm of said shaft and with said lever, substantially as specified.

696,644. GLOBE-HOLDER ATTACHMENT FOR GAS-FITTINGS. JOHN KIRBY, Jr., Dayton, Ohio, assignor to the Dayton Manufacturing Company, Dayton, Ohio. Filed Jan. 15, 1902. Serial No. 85,798. (No model.)

Claim.—1. The combination with a gas arm or bracket, of a globe-holder consisting of an anteriorly-screw-threaded inner ring the inner wall of which is of greater diameter at the top than at the bottom thereof thus forming a circumferential incline, a circular-shouldered spiral spring resting on said incline, an outer ring having an inwardly-turned flange which engages the top side of the said spring and an interior screw-thread which

engages the exterior screw-thread of the said inner ring whereby elevating and lowering the said outer ring will increase the diameter of said spring to correspond with its position on the said incline, and means for supporting the said holder at the free end of said gas arm or bracket, substantially as and for the purpose set forth.

2. A gas arm or bracket, in combination with a globe and holder therefor supported at the free end of said arm or bracket and consisting of an exteriorly-screw-threaded inner ring the inner wall of which is of greater diameter at the top than at the bottom thereof thus forming a circumferential incline, a circular-formed spiral spring resting on said incline, an outer ring having an inwardly-turned flange which engages the top side of the said spring and an interior-screw-thread which engages the exterior screw-thread of the said inner ring whereby elevating and lowering the said outer ring will increase and decrease the diameter of said spring to correspond with its position on the said incline and whereby the said lowering operation will hold the globe rigidly within the holder, substantially as and for the purpose set forth.

696,645. REFRIGERATOR ATTACHMENT. ALEXANDER B. KOKERDORF, New Orleans, La. Filed July 11, 1901. Serial No. 57,574 (No model.)

Claim.—1. In a machine for holding refrigerator-tubes, the combination with a support having an open seat in one end in which the end of the tube engages, of tube-engaging devices movably mounted upon the support and arranged to engage the tube to hold it against movement upon the support, and operating mechanism for the tube-engaging devices also carried by the support.

2. In a machine for holding refrigerator-tubes, the combination with a support having a seat at one end against which a portion of the tube bears, of arms each pivoted at one end upon the support and having a finger at its other end, which fingers are located adjacent to the seat and are arranged to engage the tube to hold it against turning, and operating means for moving the arms, also carried by the support.

3. In a machine for holding refrigerator-tubes, the combination with a support, of movable arms carried by the support and having holding devices arranged to be brought into engagement with the tubes and support, and mechanism for moving said arms and the holding devices carried thereby into and out of engagement with said tubes and support.

4. In a machine for holding refrigerator-tubes, the combination with a support, of movable arms pivoted upon the support and having holding-fingers arranged to engage with the tubes and with the support, and means for operating the arms to move the fingers carried thereby into and out of engagement with said tubes and support.

5. In a machine for holding refrigerator-tubes, the combination with a hollow support, of movable arms pivoted at their lower ends within the support and having holding-fingers on the outer sides of their upper ends, said fingers being arranged to be brought into engagement with the tubes, and means for operating the holding-arms to move the fingers into and out of engagement with said tubes.

6. In a machine for holding refrigerator-tubes, the combination with a hollow support having openings in its walls contiguous to the upper end, of movable holding-arms pivoted at their lower ends within the support, and having fingers at their upper ends arranged to fit in the openings of said support, said fingers being also adapted to engage the tubes,

and means for swinging the arms and moving the fingers into and out of the openings of the support.

7. In a machine for holding refrigerator-tubes, the combination with a stationary support against which the tube bears, of arms pivoted to the support and movable toward and from each other, means for moving the arms, and tube-engaging fingers carried by and projecting from the outer faces of the arms, said fingers being arranged to engage a tube placed upon the support to prevent the movement of said tube away from the support.

8. In a machine for holding refrigerator-tubes, the combination with a support against which one end of the tube to be held bears, of holding means mounted upon the support and arranged to engage the tube to hold it against movement, positioning devices for the tube located upon the end of the support and arranged to engage the tube to hold the same against turning and in coaxial relation with the holding means.

9. In a machine for holding refrigerator-tubes, the combination with a support, of holding-arms pivoted upon the support and having fingers arranged to engage the ends of the tube, a rock-shaft journaled upon the support, an operating-lever secured to the shaft, a crank-arm also connected to the shaft, a stem connected at one end to the crank-arm, and links pivotally connected with the free ends of the holding-arms and with the stem.

10. In a machine for holding refrigerator-tubes, the combination with a hollow supporting-standard, of arms pivoted at their lower ends within the standards and having fingers at their upper ends arranged to engage the end of the tube, a rock-shaft journaled upon the standard and having an exposed end, an operating-lever mounted upon the exposed end, a crank-arm connected to the shaft within the standard, a stem having a pivotal connection with the crank-arm, and links pivotally connecting the stem and holding-arms.

11. In apparatus for holding refrigerator-tubes, the combination with a standard, of tube-engaging means mounted thereon and including movable fingers arranged to engage in openings of the tube to be held, and a centering-ring located at the upper end of the standard and provided with positioning-lugs that engage in sockets in the tube to hold the openings of said tube in coaxial relation with the movable fingers.

12. In apparatus for holding refrigerator-tubes, the combination with a hollow standard having a centering-ring at its upper end, said ring being provided with upstanding positioning-lugs, of tube-engaging means mounted within the hollow standard and including movable fingers arranged to engage the end of a tube inserted therein.

696,646. REFRIGERATOR. ALEXANDER B. KOKERDORF, New Orleans, La. Filed Oct. 7, 1901. Serial No. 77,964. (No model.)

Claim.—1. In a refrigerator of the class described, the combination with a receptacle, of a tube passing through the receptacle, said tube being provided with an outstanding annular flange that bears against one of the outer faces of the receptacle, the other end of said tube being internally threaded, a holding-collar screwed into the threaded end of the tube and provided upon its exterior face with an annular flange that bears against the adjacent face of the receptacle, and end walls closing the ends of the tube.

2. In a refrigerator of the class described, the combination with a receptacle, of a tube passing through the receptacle, said tube being provided at one end with an outstanding annular flange that bears against the adjacent outer face of the receptacle, the other end of the tube being internally threaded, a holding-collar screwed into the threaded end of the tube and provided upon its exterior face with an annular flange that bears against the adjacent outer face of the receptacle, said collar being provided with a wall that closes the end of the tube, and a cap detachably fitted over the opposite end of the tube.

3. In a refrigerator of the class described, the combination with a

receptacle having oppositely-disposed openings, of bushings located in the openings, a tube passing through the receptacle and fitting in the bushings, one end of said tube being provided on its exterior face with an annular flange, the opposite end having internal screw-threads, packing interposed between the flange and bushing, a cap located over the end of the tube and detachably secured to said flange, a head screwed into the threaded end of the tube and provided with an exterior annular flange, packing interposed between this latter flange and the adjacent bushing, and a valved vent located in said head.

696,647. DEVICE FOR PURIFYING WATER. JEAN M. A. LACOMBE, Brooklyn, N. Y., assignor, by direct and mesne assignments, of two-thirds to Walter Lander, Brooklyn, N. Y., and James L. Heshett, Louisville, Ky. Filed Oct. 24, 1901. Serial No. 73,797. (No model.)

Claim.—1. The combination with two outer electrodes of the same polarity, of a third or intermediate electrode of opposite polarity, a double sparking-coil, two like poles of the secondary coils of which are electrically connected to said intermediate electrode, and the other poles to the two outer electrodes, the primary coil being connected with a suitable source of electricity, substantially as described.

2. In a device for the purification of water, the combination with a pipe or main having openings therein, of electrodes fitting in said openings and connected with a suitable source of electricity, and means for closing the openings in said main during the insertion or withdrawal of said electrodes, substantially as described.

3. In a device for the purification of water, the combination with a pipe or main, of tubes fitted in openings in said main and extending inwardly into the latter, electrodes removably held in said tubes and connected with a suitable source of electricity, and valves connected with said tubes for closing the same during the insertion or withdrawal of said electrodes, substantially as described.

4. In a device for the purification of water, the combination with a pipe or main, of tubes fitted in openings in said main and extending inwardly into the latter, electrodes adjustably contained within said tubes and having removable discharging points or ends, said electrodes being connected with a suitable source of electricity, and valves connected with said tubes whereby the latter may be closed during the insertion or withdrawal of said electrodes, substantially as described.

5. In a device for the purification of water, the combination with a pipe or main, of tubes fitted in openings in said main and extending inwardly into the latter, electrodes threaded into said tubes, and provided with removable discharging points or ends, said electrodes being connected with any suitable source of electricity, gate-valves located in said tubes and having valve-rods extending outwardly through said main whereby said tubes may be closed against the escape of water from said main during the insertion or withdrawal of said electrodes, substantially as described.

696,648. VEHICLE SEAT-LOCK. CHRISTIAN E. LAMBERT, Evansville, Ind. Filed Dec. 28, 1901. Serial No. 87,000. (No model.)

Claim.—1. A seat-lock for vehicles, comprising a yoke pivoted to the sill of the vehicle-body, a toggle-lever having a bifurcated upper end pivoted to said yoke, a link pivotally attached between the arms of said toggle-lever, and a hook on the seat with which said link is adapted to be detachably engaged.

2. A seat-lock for vehicles, comprising a U-shaped yoke pivoted to the vehicle-body and having inwardly-turned upper ends, a toggle-lever having a bifurcated upper end pivoted on said ends of the yoke, a link pivoted between the arms of the lever and having a loop at its upper end, and a hook on the seat with which said loop can engage detachably.

3. A seat-lock for vehicles, comprising an eyebolt adjustably fastened to the sill of the vehicle-body, a U-shaped yoke pivoted to said eyebolt, a toggle-lever having a bifurcated end provided with notches and

pivotally attached to and between the arms of said yoke, a link having laterally-projecting transverse pivotally engaging notches in the toggle-lever, and a hook on the seat with which said link can be detachably engaged, said link and its pivots being adapted to swing between the arms of said yoke in the operation of locking the seat, so as to pass the dead-center.

696,649. HORSESHOE. GEORGE A. LOW, Amesbury, Mass. Filed Jan. 4, 1902. Serial No. 33,488. (No model.)

Claim.—A horseshoe having flat top and bottom surfaces, a mortise extending through the thickness of the shoe from one of said surfaces to the other, said mortise having an inwardly-projecting tongue at one end, a dovetailed wedge-shaped keyway formed in the under side of the shoe and extending across said mortise at the end opposite said tongue, a nail having a tenon with an outwardly-projecting tongue at one end adapted to engage the tongue in the mortise, and a wedge-shaped key fitted in said keyway and arranged to bear on the tenon to hold the same in engagement with the mortise-tongue, the length of said key exceeding the width of the shoe, so that the smaller end of the key is adapted to be bent upwardly against one edge of the shoe to prevent endwise movement of the key in one direction, the wedge shape of the keyway and key preventing endwise movement of the key in the opposite direction, and causing the key to force the tenon endwise against the shouldered end of the mortise.

696,650. SKIRT-SUPPORTER. JAMES MAYHEW, Boston, Mass. Filed July 13, 1901. Serial No. 68,257. (No model.)

Claim.—1. An appliance of the character specified comprising a single piece of wire having a horizontal central portion and double-acting hooks at the ends of the central portion, said hooks being connected with the said central portion by outwardly and oppositely bent loops adapted to support the appliance from a piece of fabric and having upwardly-projecting penetrating points or spurs.

2. An appliance of the character specified comprising a single piece of wire having a central portion, two upper loops formed at the ends of the central portion and bent outwardly in opposite directions, and two lower hooks forming continuations of and depending from the upper loops and provided with penetrating points or spurs.

3. A skirt-supporter comprising a wire member having a central portion with an integral loop at each end and a downwardly and upwardly

extending back integral with each loop, and a plate secured to said member and forming a shield in the rear of the hooks, the said hooks bearing against the face of the plate.

696,651. COMBINED BADGE AND PENCIL-HOLDER. JOHN A. MARSHALL, Mountville, W. Va. Filed July 6, 1901. Serial No. 67,385. (No model.)

Claim.—1. A device of the character specified comprising a pencil-holder and garment-engaging means, and a button or badge detachably connected with the said means.

2. A device of the character specified comprising two oppositely-flexed members constituting a pencil-clamp, garment-engaging means carried by one of the members, and a button or badge detachably engaging said means.

3. A device of the character described, comprising a pair of spring-jaws, a garment-piercing member carried by one of the jaws, and a badge or button detachably applied to the garment-piercing member to prevent accidental displacement thereof.

4. A device of the character described, comprising a pair of spring-jaws, a two-tined garment-piercing member carried by one of the jaws, and a button or badge detachably embracing the tines of the garment-piercing member.

5. A device of the character specified comprising a three-membered structure, whereof two members constitute a pencil-clamp, and the third member a garment-piercing and engaging means, and a badge or button detachably engaging the third member.

6. A device of the character described, comprising a pair of looped jaw members having their corresponding ends provided with spring connections, a garment-piercing member carried by one of the jaw members, and a button or badge detachably carried by the garment-piercing member.

7. A device of the character specified, constructed of a piece of wire bent to form two resilient loops constituting a pencil-clamp, the terminals of the wire constituting pins to pass through a garment, and a button having a hollow back detachably engaging the pins.

8. A device of the character described, comprising two loops having a spring connection and arranged within the garment, garment-engaging means connected to the crest of one loop and exposed on the outside of the garment, and a button adapted to be secured to the exposed portion of the garment-engaging means.

9. A device of the character described, comprising the two loops having a spring connection at one end, garment-engaging pins extended from one of the loops, and a sleeve arranged at the junction of the pins with the loop.

10. A device of the character described, comprising a pair of inverted substantially U-shaped jaw members, which have their corresponding ends connected by spring-calls, the members being divergent from their spring connections, a pair of garment-piercing lines carried by the outer end of one of the jaws and a hollow button or badge detachably snapped upon the lines.

696,652. DENTAL OUTLINDER. ALVIN F. KIRKMAN, Jr., Oakland, Cal. Filed Feb. 27, 1900. Serial No. 4,754. (No model.)

Claim.—1. In combination with a handpiece for operating upon a patient, means for relieving the pain of the operation, comprising a tube attached thereto having a nozzle directed to the point operated upon, a

supply of water under constant pressure, a reservoir, means for heating water in said reservoir, a coil of pipe in said reservoir connected at one end with the water-supply, and a flexible connection from the other end of the coil to the tube, substantially as described.

2. In combination with a handpiece for operating upon a patient, means for relieving the pain of the operation, comprising a tube attached thereto having a nozzle directed to the point operated upon, a reservoir, a coil of pipe in said reservoir, means for heating water in said reservoir, a flexible connection from the coil of pipe to the tube, two water-supply pipes, one connected to the reservoir and the other connected to the coil of pipe therein, and a filter in said last-mentioned water-supply pipe, substantially as described.

696,658. BRAKE FOR VEHICLES. WILLIAM G. FROST, Kingston, N. Y., assignor to Columbia Brake & Supply Company, Chicago, Ill., a Corporation of Illinois. Filed July 12, 1899. Serial No. 723,067. (No model.)

Claim.—1. A brake mechanism, comprising a part on the axle, an opposed frictional device, a stop device in proximity thereto, two parts interposed between said frictional device and said stop device, one of the parts engaging one device at two separated pivotal bearing-points and engaging the other part at two separated pivotal bearing-points, the several points disposed about the axle, so that said parts are free to rock about each other without varying the position of the friction device, substantially as described.

2. A brake mechanism, comprising a part fixed to the axle, an opposed frictional element, brake-applying devices operatively connected with said frictional element, a stop in proximity to said frictional element, an actuating device between the stop and the frictional element for moving said frictional element toward the fixed part, a compensating or adjusting device so part of the actuating device but interposed between the stop and said frictional part, which permits an automatic rocking upon axes approximately at right angles to each other, whereby automatic adjustment for inequalities in the construction is obtained.

3. A brake mechanism, comprising a part fixed to the axle, an opposed frictional part, brake-applying devices operatively connected with said frictional part, a stop in proximity to said frictional part, an actuating device between the stop and the frictional part for moving said frictional part toward the fixed part, a gimbal between the stop and the working face of the frictional part, and an armature part on the car for operating said actuating device, said gimbal having no effective function in moving said frictional part toward the fixed part, but effectively brought into action after the said frictional and fixed parts are in engagement.

4. A brake mechanism, comprising a part on the axle, an opposed frictional device, a stop device in proximity thereto, two parts interposed between said frictional device and said stop device, one of said parts hav-

ing a rocking connection at two points with one device and at two differently-located points with the other part, so that said parts are free to rock about each other to adjust themselves to varying conditions and without varying the position of said frictional device, and means for moving said parts with relation to each other so as to move the frictional element.

5. A brake mechanism, comprising a part on the axle, an opposed frictional device, a stop device in proximity thereto, two parts interposed between said frictional device and said stop device, one of said parts having a rocking connection at two points with one device and at two differently-located points with the other part, thus forming four points of pressure, one of said latter connections comprising a movable piece working in one of said parts and engaging the other, and a controlling device connected with said movable piece so as to actuate it and separate the two parts.

6. A brake mechanism, comprising a part on the axle, an opposed frictional device, a stop device in proximity thereto, two relatively movable parts interposed between said frictional device and said stop device, one of said parts having a rocking connection at two points with one device and at two differently-located points with the other part, one of said latter connections comprising a movable piece working in one of said parts, a rotatable part engaging said movable piece, said rotatable part operatively connected with a controlling device by means of which the mechanism is operated.

7. A brake mechanism, comprising a part on the axle, an opposed frictional device, a stop device in proximity thereto, two parts interposed between said frictional device and said stop device, one of said parts having a rocking connection at two points with one device and at two differently-located points with the other part, one of said latter connections comprising a piece movably mounted on one of said parts, an opposed adjustable piece on the other part engaging said movable piece, and a controlling device to which said movable piece is connected.

8. A brake mechanism, comprising a part on the axle, an opposed frictional device, a stop device in proximity thereto, two parts interposed between said frictional device and said stop device, one of said parts having a rocking connection at two points with one device and at two differently-located points with the other part, said four points of connection being disposed about the axle substantially ninety degrees apart and adapted to permit a rocking motion of the movable parts when there are irregularities in the devices between which they are interposed without varying the position of said frictional device, and means for moving said two parts with relation to each other so as to move the frictional element to an operative position.

9. A brake mechanism, comprising a fixed element on the axle, a frictional element opposed thereto, two parts associated with said frictional element and interposed between it and a stop, a device for moving said parts relatively so as to force the frictional element against the fixed element on the axle, a controlling device on the vehicle-body and an automatic adjustable connection between said controlling device and the device for moving said parts.

10. A brake mechanism, comprising a fixed element on the axle, a frictional element opposed thereto, two parts associated with said frictional element and interposed between it and a stop, a device for moving said parts relatively so as to force the frictional element against the fixed element on the axle, a controlling device on the vehicle-body, a connection between said controlling device and the device for moving said parts, and a compensating device in said connection for compensating for the relative movement of the vehicle-body and the axle.

11. A brake mechanism, comprising a fixed element on the axle, a frictional element opposed thereto, two parts associated with said frictional element and interposed between it and a stop, a device for moving said parts relatively so as to force the frictional element against the fixed element on the axle, a controlling device on the vehicle-body, a connection between said controlling device and the device for moving said parts, two reciprocating parts interposed in said connection and adapted to reciprocate with relation to each other, said parts connected so as to rotate together.

12. A brake mechanism, comprising a fixed element on the axle, a frictional element opposed thereto, two parts on the axle and interposed between the frictional element and a stop, a device for moving one of said parts so as to force the frictional element against the fixed element on the axle, a controlling device on the vehicle-body, a connection between said controlling device and the device for moving said parts, two reciprocating parts interposed in said connection and adapted to reciprocate with relation to each other, said parts connected so as to rotate together, one of said parts having a universal connection with the controlling device and the other part having a universal connection with the device for moving the part on the axle so as to move the frictional element.

13. A brake mechanism, comprising an actuating device on the vehicle-axle, a controlling device on the vehicle-body, a connection between the actuating device and the controlling device, two parts interposed in

said connection and free to reciprocate with relation to each other, but connected so as to move together when rocked about their axes.

14. A brake mechanism, comprising an actuating device on the vehicle-axle, a controlling device on the vehicle-body, a connection between the actuating device and the controlling device, two parts interposed in said connection and free to reciprocate with relation to each other, but connected so as to move together when rocked about their axes, one of said parts connected with the vehicle-body by a universal connection and a universal connection between the other part and said actuating device.

15. A brake mechanism, comprising two parts interposed between a stationary and a movable piece, a plunger associated with one part and bearing against the other part, a cam engaging said plunger and adapted to move it so as to separate the parts.

16. A brake mechanism, comprising two parts interposed between a stationary and a movable piece, a plunger associated with one part, an adjustable device on the other part which said plunger engages, a cam engaging said plunger and adapted to move it so as to separate the parts.

17. A brake mechanism, comprising a fixed element on the axle, a frictional element opposed thereto, two parts interposed between said frictional element and a stop on the axle, said parts provided on one side of the axle with means for separating them, a piece on the other side of the axle connected with one of said parts and bearing against the other, and one or more washers interposed between said piece and one of said parts, so as to hold the parts in their adjusted relative position.

18. A brake mechanism, comprising a fixed element on the axle, an opposed frictional element, two parts on said axle interposed between said frictional element and a stop associated with the axle, means for separating said parts located on one side of the axle and a connection or fulcrum between the parts on the other side of the axle.

19. A brake mechanism, comprising a fixed element on the axle, a frictional device opposed thereto, two parts interposed between said frictional device and a stop device on the axle, one part engaging the stop device and the other part, said other part engaging the frictional device, the several engagements forming pivotal connections, means for separating said two parts so as to move the frictional device against the fixed element on the axle, the engagement between said two parts and the stop and frictional element being such as to permit a rocking movement of said parts without moving the frictional device or varying the pressure with which the frictional element is forced against the fixed element on the axle.

20. A brake mechanism, comprising a fixed element on the axle, a frictional element opposed thereto, a stop on the axle, two parts interposed between said frictional element and said stop, said parts provided on one side of the axle with means for separating them, a bolt on the other side of the axle adjustably connected with one of said parts and bearing against the other, the position of said bolt adapted to be adjusted by means of one or more washers placed between the head of the bolt and the part with which it is connected, substantially as described.

21. A brake mechanism, comprising a fixed part on the axle, an opposed frictional element, a stop associated therewith, two parts on said axle interposed between said stop and said frictional element, one of said parts provided with a projecting arm which passes through an opening in a stationary part of the car, the other part provided with projecting lugs which engage the first-mentioned part, the construction arranged so as to prevent the two parts from rotating with the axle but permit relative movement between them.

22. A brake mechanism, comprising a fixed part on the axle, an opposed frictional device, a stop device on said axle, two parts mounted upon said axle and interposed between said stop device and frictional device, one of said parts connected at two points by a rocking connection with one device, the two parts connected together at two points substantially ninety degrees from said first-mentioned points, one or both of said parts provided with a projecting end which engages a part of the car so as to prevent the rotation of the parts with the axle.

23. A brake mechanism, comprising a fixed part on the axle, an opposed frictional device, a stop device associated therewith, two parts interposed between said frictional device and stop device, two pieces, one on each side of the axle, adapted to engage one of said devices, said pieces provided with projections received into openings in one of said parts, so as to carry the pressure when the parts are separated, a connection between said parts on each side of the axle, and means for separating said parts so as to move the frictional element in contact with the fixed part on the axle.

24. A brake mechanism, comprising a fixed part on the axle, an opposed frictional element, two parts mounted on said axle between said frictional element and a stop and adjustably connected together, one of said parts provided with an enlarged or elliptical opening at the point where it engages the axle, so as to permit movement with relation to said axle.

25. A brake mechanism, comprising a fixed part on the axle, an opposed frictional element, a stop associated with said axle, two parts interposed between said frictional element and said stop, said parts con-

locked together, a spring device between the parts at this connection, and means for separating the parts so as to move the frictional element.

26. A brake mechanism, comprising a fixed element on the axle, a frictional element opposed thereto, a stop on said axle, two parts interposed between said frictional element and said stop, one of said parts connected at two points either with the frictional element or stop, or some part associated therewith, and at two differently-located points with said other part, said four points of connection being substantially ninety degrees apart and adapted to permit a rocking motion of the movable parts to compensate for irregularities in the devices between which they are interposed, an actuating device for separating said two parts, a plunger associated with one part and bearing against the other, a cam engaging said plunger and adapted to move it to separate the parts, a telescopic connecting-link between said cam and a controlling device on the vehicle-body, said link connected to said parts at each end by a universal connection.

27. A brake for cars, comprising a friction device on the axle, an operating device on the car-body, a rotatable rod adjustable longitudinally, interposed between the operating device and the friction device, the rotation of said rod actuating the friction device.

28. A brake for cars, comprising a friction device on the axle, an operating device on the car-body, a rotatable telescopic two-part rod interposed between the operating device and the friction device, one part being connected with the friction device and the other part with the operating device on the car, the rotation of said rod actuating the friction device.

29. The combination with a car and its brake, of independent trucks pivotally supporting the ends of the car, a brake-operating friction-clutch upon one axle, clutch-operating devices supported by the truck, a pivoted lever supported from the car near said axle, means whereby a brakeman at the end of the car may swing said lever, at will, and connections of automatically-adjustable length transmitting the rotary motion of the lever to said devices, whereby said devices are operated regardless of relative swinging of the truck.

30. The combination of a car and its truck, of a brake-operating friction-clutch upon one truck-axle, devices supported by the truck alone, for throwing the clutch into engagement, a sleeve mounted in a bearing supported from the car and adapted to both swing and rotate, a bar sliding but not rotating in said sleeve, means whereby the rotation of the bar actuates said devices, and means whereby said sleeve may be rotated from either end of the car.

31. The combination with a car and its truck, of a brake-operating friction-clutch upon one of the axles, a brake-staff at the end of the car, a sleeve adapted to swing and to rotate and mounted in a bearing supported by the car alone, a bar sliding but not rotating in said sleeve, means whereby said sleeve and bar may be rotated by the movement of the brake-staff, and means whereby the rotation of the bar throws said clutch into engagement.

698,654. BRAKE FOR VEHICLES. WILLIAM C. FRANK, Kingston, N. Y., assignor to Columbia Brake & Supply Company, Chicago, Ill., a Corporation of Illinois. Filed July 26, 1901. Serial No. 99,709. (No model.)

Claim.—1. In a brake for vehicles, the combination of a friction device on the axle, with setting devices carried on the axle and adapted to be operated by a liquid under pressure, a liquid-supply device carried on the vehicle-body, a liquid-compressing device associated therewith, a liquid-transmitting device from the liquid-supply device to the friction device to operate the same responsive to the motion of the liquid-compressing device, and a separate connection from the liquid-storage to the friction device for the transmission of the liquid for lubricating the parts.

2. In a brake for vehicles, the combination of a friction device on the axle, with setting devices carried on the axle and adapted to be operated by a liquid under pressure, a lubricating-liquid-supply device carried on the vehicle-body, a liquid-compressing device associated therewith, a liquid-transmitting device from the liquid-supply device to the friction device to operate the same responsive to the motion of the liquid-compressing device, and a separate connection from the lubricating-liquid-supply device to the friction device to transmit a portion of the liquid for lubricating purposes.

3. In a brake for vehicles, the combination of a friction device on the axle, with setting devices carried on the axle and adapted to be operated by a liquid under pressure, a liquid-supply device carried on the vehicle-body, a liquid-compressing device associated therewith, a liquid-transmitting device from the liquid-supply device to the friction device to operate the same responsive to the motion of the liquid-compressing device, and a separate connection from the liquid-storage to the friction device for the transmission of the liquid for lubricating the parts, the fluid-transmitting device leading from the liquid-supply on the vehicle-body to the friction device on the axle being flexible.

4. In a brake for vehicles, the combination of a friction device on the axle, with setting devices carried on the axle and adapted to be operated by a liquid under pressure, a lubricating-liquid-supply device carried on the vehicle-body, a liquid-compressing device associated therewith, a liquid-transmitting device from the liquid-supply device to the friction device to operate the same responsive to the motion of the liquid-compressing device, and a separate connection from the lubricating-liquid-supply device to the friction device to transmit a portion of the liquid for lubricating purposes, the fluid-transmitting device leading from the liquid-supply on the vehicle-body to the friction device on the axle being flexible.

5. In a brake for vehicles, a friction device on an axle, or other rotating part, which is operated by a hydraulic device; the hydraulic device being operated by a pump which is carried by the vehicle-body and a capillary lubricating device, the hydraulic pump and capillary lubricating devices being placed in tanks carried by the vehicle-body.

6. In a brake for vehicles, a friction device on an axle or other rotating part, a hydraulic device carried by the rotating part, a pump in a tank containing a liquid which operates the hydraulic device through a flexible pipe connection.

7. In a brake for vehicles, a friction device on a rotating part, a hydraulic device which is carried by the rotating part, a pump in a tank of liquid which operates the hydraulic device, a lever which operates the pump and connections from the pump-lever to hand-levers at each end of the car.

8. In a brake for vehicles, the combination of a brake-setting device with a power-supplying device, a connection between the same, whereby power is transmitted from the power-supplying device to the brake-setting device to set the brakes, and a lubricant-transmitter connected with the brake-setting device at one end and with the power-supplying device at the other, and a lubricant-supply associated with the power-supply.

9. In a brake, the combination of a friction-clutch device with a power-supplying device, a connection from one to the other, said power-supplying device adapted to supply power to the friction-clutch by means of lubricating fluid, and a separate lubricating connection from the power-supplying device to the friction-clutch.

10. In a brake for vehicles, a friction device carried by an axle which has a fixed part and a loose part, the axle-bearing of the loose part being taper-bored.

11. In a brake for vehicles, a friction device carried by an axle which has a fixed part and a loose part, the loose part having a bearing at each end of its hub, one bearing being larger than the other so that the loose part is free to wobble on its bearings.

12. In a brake for vehicles, a friction device on an axle which is

operated by a hydraulic device, the hydraulic device being operated by a pump which is carried by the vehicle-body, and a capillary lubricating device, the capillary lubricating device being placed in a tank carried by the vehicle-body.

13. In a brake for vehicles, a friction device carried by an axle having a fixed and loose disk, the bearing of the loose disk being taper-bored.

14. In a brake for vehicles, a friction device on an axle, which has a fixed part and a loose part, the loose part having a bearing at each end of its hub, one bearing being larger than the other, so the loose part is free to wobble on its bearings, the loose part carrying a chain which is operatively connected to the brake-chain.

15. In a brake for vehicles, a fixed friction-disk and a loose friction-disk on an axle, the loose friction-disk carrying a chain which is operatively connected to the brake-chain, the loose friction-disk having a bearing at each end of its hub, one bearing being larger than the other, so the loose friction-disk can wobble on its bearings.

16. In a brake for vehicles, a friction device on an axle, which is operated by a liquid-pressure, a pump device which is used to produce the liquid-pressure, a reservoir containing liquid which supplies the pump, the pump and reservoir being so associated that the liquid which leaks past the pump-piston returns by gravity to the reservoir.

696,655. BALANCE ATTACHMENT FOR CENTRIFUGAL PUMPS. FRANKSON RAY, San Francisco, Cal., assignor of one-half to James Spiers, Jr., San Francisco, Cal. Filed Aug. 2, 1901. Serial No. 70,730. (No model.)

Claim.—1. An automatic balancing device for centrifugal pumps, consisting of a piston fixed upon the revolving shaft, and having annular grooves or channels around its periphery connected respectively with the upper and lower ends of the piston, a chamber within which the piston is revolvable, said chamber having an annular groove or channel connecting with the discharge of the pump, and so located that the rise or fall of the shaft and parts carried thereby will open communication through the grooves to either end of the cylinder.

2. A balancing device for centrifugal pumps consisting of a cylinder having an annular groove around the interior and connections between said groove and the discharge of the pump, a piston or disk revolvable within the cylinder having annular parallel grooves located respectively above and below the groove in the cylinder, connections between one of said piston-grooves, and the upper end of the cylinder, and between the other groove and the lower end whereby movement of the piston in either direction opens communication between the corresponding end of the cylinder and the pressure-groove.

3. A balancing device for centrifugal pumps consisting of a cylinder concentric with the revolvable runner-shaft, a disk or piston carried by said shaft revolvable within the cylinder, chambers surrounding the shaft at opposite ends of the cylinder, corresponding extensions of the piston slidable within said chambers, an open connection between the chambers and with the suction of the pump, an annular groove around the interior of the cylinder connected with the discharge of the pump, parallel grooves made around the piston above and below the groove of the cylinder, one of said grooves having connection with the upper end of the cylinder, and the other with the lower end whereby either of said grooves may be caused to overlap the pressure-groove of the cylinder and communicate pressure to the end of the cylinder with which it is connected.

696,656. AUTOMATIC AND INSTANTANEOUS APPARATUS FOR PRODUCING PHOTOGRAPHS. FRANKSON RAY, San Francisco, Cal., assignor of one-half to James Spiers, Jr., San Francisco, Cal. Filed Feb. 2, 1902. Serial No. 4,912. (No model.)

Claim.—1. A system of automatic and instantaneous apparatus for producing completely-finished photographs having in combination a clock-work-movement with a fly-regulator for actuating the apparatus and apparatus comprising a wheel having a stop-notch on the rim, an elbow-lever 27 adapted to drop with its point in said notch at the end of each revolution of the said wheel and carrying a finger which thereupon engages a wing of the fly and thus arrests the movement, a rod 23 adapted to be operated from the exterior and having an inclined piece adapted to bear on the bottom of an elbow-lever and lift it in order to release the wing of the fly to restart the movement, a vertical shaft operated by the clock-work-movement, and having at the top a crank with a link for pushing a sensitive plate in a dark chamber, and a hinged basket for receiving the exposed plate, substantially as hereinbefore set forth.

2. In an automatic apparatus for producing finished photographs, the combination of a rectangular tube 4 adapted to contain a large number of thin-metal frames bent over at the edges for retaining the sensitive plates, a recessed casing to receive said tube and provided with a support in which slides a pusher, a rod connected with a crank carried by the operating-spindle and rod adapted to move said pusher beneath the tube and cause a frame to fall in the dark chamber 19 toward the objective, and a spring placed between the tube and the frame at its exit to prevent any sliding of the latter, substantially as described.

3. In an automatic apparatus for producing finished photographs the combination of a basket 25, a dark chamber 19, a slide adapted to support plates in said chamber, an elbow-rod 23 adapted to encounter the slide and discharge a plate into the basket, a series of balls separated by partitions, means for raising the basket over the partitions, said means comprising a cam-arm carrying the basket, a spindle on which it is mounted, an elbow-lever having its upper arm bearing on the cam-arm, rolls adapted to be encountered by the lower arm of the lever, and a stud on said cam-arm for arresting the basket in its lower position.

4. In an automatic apparatus for producing photographs the combination with a pivoted basket, of means for moving it in a predetermined path, a fixed guide-track 25 extending outward of the path of the basket adapted to be encountered by the basket and serving to tilt the same on its axis and discharge its contents.

696,657. WIFT-REFILLING MECHANISM FOR LOOMS. JEREMIAH H. SHAY, Fall River, Mass., assignor of one-half to A. B. Fitch Machinery Company, Providence, R. I., a Corporation of Rhode Island. Filed Aug. 12, 1902. Serial No. 27,048. (No model.)

Claim.—1. In a loom, the combination of a lay having a movable shuttle-box, a filling-detector, a stationary shuttle-reservoir independent of the lay and located in a position vertically above the end of the lay when the lay reaches the limit of its backward movement, a shuttle-transferer operative upon the failure of the filling-thread in the shed to move forward toward the breast-beam the lowest shuttle in the reservoir and place the same in said shuttle-box, and connections between the filling-detector and shuttle-box adapted to move said shuttle-box into position for the reception of said shuttle as the lay completes its backward motion, substantially as specified.

2. In a loom, the combination of a lay having a movable shuttle-box, a filling-detector, a stationary shuttle-reservoir independent of the lay and located in a position vertically above the end of the lay when the lay reaches the limit of its backward movement, a shuttle-transferer operative upon the failure of the filling-thread to move a shuttle from said reservoir directly into the shuttle-box, and means adapted to move the shuttle-box into position for the reception of said shuttle and to return said shuttle-box to its normal position upon the lay, substantially as described.

3. In a loom, the combination of a lay having a movable shuttle-box, a filling-detector, a stationary shuttle-reservoir independent of the lay and located in a position vertically above the end of the lay when the lay reaches the limit of its backward movement, a shuttle-transferer operative upon the failure of the filling-thread to move a shuttle from said reservoir into the shuttle-box as the lay completes its backward motion, and means adapted to move the shuttle-box so as to place the shuttle therein contained in operative position upon the lay during the next forward beat of the lay, substantially as shown.

4. In a loom, the combination of a lay having a movable shuttle-box, a filling-detector, a stationary shuttle-reservoir independent of the lay and located in a position vertically above the end of the lay when the lay reaches the limit of its backward movement, a shuttle-transferer operative upon the failure of the filling-thread to move a shuttle forward through the front of the shuttle-reservoir through the bottom of the shuttle-box, and means adapted to move the shuttle-box so as to place the shuttle therein contained in operative position upon the lay, substantially as specified.

5. In a loom, the combination of a lay having a movable shuttle-box, a filling-detector, stationary means independent of the lay to support one or more shuttles, a shuttle-transferer located at the rear of the shuttle-supporting means and adapted to engage and transfer a shuttle from the shuttle-supporting means to the shuttle-box, together with means adapted to move the shuttle-box so as to place the shuttle therein contained in operative position, during the next forward movement of the lay, substantially as set forth.

6. In a loom, the combination of a lay having a movable shuttle-box, a filling-detector, a stationary shuttle-reservoir mounted above the plane of the lay and independent of the lay, a shuttle-transferer mounted movably upon a rearward projection of the shuttle-reservoir, and means operative upon the failure of the filling-thread to actuate the transferer and move a shuttle forward from the shuttle-reservoir into the shuttle-box, substantially as shown.

7. The combination of a shuttle-transferer and a shuttle-reservoir for looms, the latter comprising an upright box, open at its top, lower front, lower rear and middle front and a projection at its lower rear end, which is adapted to support said shuttle-transferer, substantially as specified.

8. In a loom, the combination of a lay having a movable shuttle-box, a stationary shuttle-reservoir independent of the lay and open at its top, lower front, lower rear and middle front, yielding detents at its lower front ends arranged to prevent the lowest shuttle from displacement in the shuttle-reservoir by the vibrations of the loom, a rocker-arm for fastening the ends of the wale which extend from the shuttles in the shuttle-reservoir, and a shuttle-transferer at the lower rear end of the shuttle-reservoir and adapted to engage the lowest shuttle in the shuttle-reservoir and to force the same therefrom into the shuttle-box upon failure of the filling-thread, substantially as described.

9. The combination of a shuttle-reservoir, a shuttle-box and a shuttle-transferer movably mounted in the rear of the shuttle-reservoir and adapted to engage the lowest shuttle in said reservoir and move said shuttle forward through the front of the reservoir and through the bottom of the shuttle-box as the lay completes its backward motion, substantially as described.

10. The combination of a shuttle-box having a binder, a shuttle-transferer, and means to operate the same upon failure of the filling-thread so as to place one end of a shuttle in the shuttle-box to displace the free end of the binder and while holding said end of the shuttle in the shuttle-box to press the other end of the shuttle therein, substantially as shown.

11. In combination with a shuttle-box, a shuttle-transferer, means adapted to operate the transferer so that when transferring a shuttle to

the shuttle-box said shuttle enters the shuttle-box at an angle with the opening in the shuttle-box and means adapted to move said shuttle after it has so entered the shuttle-box into operative position therein, substantially as set forth.

12. In a loom, adapted to renew its supply of filling-thread when necessary, the combination of a lay having a movable receiving shuttle-box at one end and a movable rejecting shuttle-box at the other end, a stationary shuttle reservoir independent of the lay and adjacent to the receiving shuttle-box when the lay is at the end of its rearward motion and containing a supply of shuttles each provided with filling-thread, a stationary shuttle-receiving pan independent of the lay and adjacent to the rejecting shuttle-box when the lay is at the end of its rearward motion, a filling-detector, and means adapted to effect the ejection of the spent shuttle from the last-named shuttle-box into said receiving-pan and the transfer of a fresh shuttle from the shuttle-reservoir to the receiving shuttle-box, which means derive motion from the filling-detector and operate simultaneously, substantially as specified.

13. In a loom, the combination of a lay having a movable shuttle-box, a filling-detector, a stationary shuttle-receiving pan independent of the lay located in a plane above that of the shuttle-box, projecting over the shuttle-box and adjacent thereto, and connections between the filling-detector and the shuttle-box adapted to move said shuttle-box into the plane of said pan and to eject the shuttle from the shuttle-box into said pan as the lay completes its backward movement, substantially as specified.

14. In a loom, the combination of a lay having a movable shuttle-box with a binder, a filling-detector, a stationary shuttle-receiving pan independent of the lay and adjacent to the shuttle-box, connections between the filling-detector and shuttle-box adapted to move said shuttle-box in the arc of a circle, and means adapted to release the pressure of the binder on the shuttle in the shuttle-box as the lay completes its backward movement, substantially as described.

15. In a loom, the combination of a lay having a movable shuttle-box, a filling-detector, a stationary receiving-pan independent of the lay, located above the plane of the shuttle-box and adjacent to the shuttle-box, a shuttle-transferer, and connections between the filling-detector and the shuttle-box adapted to move the shuttle-box into position for the transferer to remove the shuttle from the shuttle-box as the lay completes its backward motion, substantially as shown.

16. In a loom, the combination of a lay having a movable shuttle-box provided with a binder, a filling-detector, a stationary shuttle-receiving pan independent of the lay and adjacent to said shuttle-box, a shuttle-transferer mounted movably on the receiving-pan, and connections between the filling-detector and the shuttle-box adapted to move said shuttle-box in the arc of a circle, to move the binder out of position and to move the transferer into the shuttle-box and eject the shuttle therefrom and also to return said shuttle-box to its normal position upon the lay during the forward motion of the lay, substantially as specified.

17. In a loom, the combination of a lay having a movable shuttle-box, a filling-detector, a stationary receiving-pan independent of the lay, a shuttle-transferer, and means operative upon the failure of the filling-thread to move said transferer so as to transfer a shuttle from the shuttle-box into the receiving-pan, substantially as described.

18. In a loom provided with means to renew its supply of filling-thread when necessary, the combination of a lay, a movable shuttle-box thereon, open at its bottom, shuttle-exPELLING mechanism adapted to compel the exit of a shuttle through the bottom of the shuttle-box in a plane above the normal plane of the shuttle-box, a filling-detector, and means intermediate between it and the shuttle-box to operate said shuttle-box and said shuttle expelling mechanism, upon failure of the filling, substantially as shown.

19. In a loom provided with means to renew its supply of filling-thread when necessary, the combination of a lay, a picker and picker-stick, a movable shuttle-box thereon open at its top and bottom, a filling-detector and means between said detector and shuttle-box operative upon failure of the filling-thread to move the shuttle-box so as to place the shuttle therein contained above and to one side of the picker and to remove said shuttle from the shuttle-box, substantially as described.

20. In a loom provided with means to renew its supply of filling-thread when necessary, the combination of a lay, a picker and picker-stick, a movable shuttle-box upon the lay and having a binder, a filling-detector, and means between the filling-detector and shuttle-box operative upon failure of the filling-thread to move the shuttle-box so as to place the shuttle contained therein above and to one side of the picker and release the pressure of the binder upon the shuttle so as to eject the shuttle from the shuttle-box, as the lay completes its backward motion, substantially as specified.

21. In a loom, the combination of a lay, a vertically-movable shuttle-box comprising two longitudinal sides and an end and provided with a binder, a flat spring secured to the shuttle-box and bearing against the

binder, an inward projection from the top edge of the shuttle-box, and a movable inward projection from the bottom edge of the shuttle-box slightly below said bottom edge and extending beneath the path of motion of the shuttle for the purpose of supporting the shuttle in the shuttle-box while said shuttle-box is rising from the lay, substantially as described.

22. In a loom provided with means to supply a fresh shuttle upon failure of the filling-thread, the combination of a lay, a picker and picker-stick, a filling-detector, a vertically-movable shuttle-box, having a flat spring fastened to its side and projecting within the shuttle-box and located in a line slightly below the bottom of the shuttle-box, and a cam fastened on the lay and adapted to hold the projecting end of the spring below the path of motion of the shuttle and retain the shuttle in the shuttle-box against the pressure of the picker on the point of the shuttle while the shuttle-box is rising from the lay and to allow said spring to withdraw from beneath the shuttle after the shuttle is raised above the picker, substantially as specified.

23. In a loom provided with means to supply a fresh shuttle upon failure of the filling-thread, the combination thereof of a shuttle-receiving pan or reservoir fastened to the side frame or arch of the loom above the normal path of motion of the ejection shuttle-box projecting over said shuttle-box and adjacent thereto and adapted to receive a spent shuttle when ejected from the shuttle-box, substantially as specified.

24. In a loom provided with means to renew its supply of filling-thread when necessary, the combination of a receiving pan or reservoir fastened to the frame of the loom above the normal path of motion of the shuttle-box and adjacent thereto, and a movable ejector supported on said pan or reservoir, and operative upon failure of the filling-thread to remove the spent filling-carrier from the shuttle-box into the receiving pan or reservoir, substantially as described.

25. In a loom, the combination of filling-supplying mechanism and mechanism operative upon failure of the filling to effect the delivery of a fresh supply of filling at one end of the lay and to eject the spent filling-carrier at the other end as the lay completes its backward motion, substantially as set forth.

26. In a loom, the combination of filling-supplying mechanism, and mechanism operative upon failure of the filling to effect the delivery of a fresh supply of filling through the bottom of the shuttle-box into said shuttle-box at one end of the lay and to eject the spent filling-carrier through the bottom of the shuttle-box at the opposite end of the lay as the lay completes its backward motion, substantially as described.

27. In a loom provided with means to furnish a fresh supply of filling-thread when necessary, the combination of a lay, a push-plate and means to operate the same, a movable shuttle-box on the lay, a filling-detector and means actuated thereby and operative upon failure of the filling-thread to rotate the shuttle-box one-fourth of a revolution for the purpose of enabling said push-plate to enter said shuttle-box and positively eject the filling-carrier through the bottom of the shuttle-box as the lay completes its backward motion, substantially as shown.

28. In a loom provided with means to furnish a fresh supply of filling-thread when necessary, the combination of a lay, a push-plate and means to operate the same, a movable shuttle-box on the lay, a filling-detector and means to rotate the shuttle-box one-fourth of a revolution for the purpose of enabling said push-plate to enter said shuttle-box and positively eject the spent filling-carrier therefrom through the bottom of the shuttle-box as the lay completes its backward motion, and means adapted to return said shuttle-box to its normal position as the lay comes forward, substantially as specified.

29. In a loom, the combination of a lay, a movable shuttle-box on each end of the lay, a reservoir properly supported in the rear of one of said shuttle-boxes but independent of the lay, a receiving-pan properly supported in the rear of the other shuttle-box but independent of the lay, and filling-supplying mechanism operative upon failure of the filling to effect the delivery of a fresh supply of filling from said reservoir into the shuttle-box adjacent thereto and to eject the spent filling-carrier from the opposite shuttle-box into the receiving-pan as the lay completes its backward motion and to return both said shuttle-boxes to their normal position as the lay comes forward, substantially as shown.

30. In a loom, the combination of a lay, a filling-detector, a movable shuttle-box on each end of the lay, pivoted in suitable bearings attached to the lay, and mechanism operative upon failure of the filling to move said shuttle-boxes slowly degrees upon their bearings while the lay is moving in one direction and to return them to their normal position while the lay is moving in the opposite direction, substantially as described.

31. In a loom, the combination of a lay, a filling-detector, a movable shuttle-box at each end of the lay mounted upon suitable bearings attached to the front of the lay, and means in connection with the filling-detector to simultaneously move both said shuttle-boxes one-fourth of a revolution during the backward motion of the lay and to return said shuttle-boxes to their normal position during the forward movement of the lay, substantially as specified.

32. In a loom provided with means to supply a fresh shuttle upon failure of the filling-thread, the combination thereof of a lay, a push-plate and means to operate the same, a movable ejection shuttle-box pivotally mounted at or near its two front lower corners in suitable bearings attached to the lay, and means operative on each failure of the filling to change the position of said shuttle-box while retaining the spent shuttle therein for the purpose of enabling the push-plate to enter said shuttle-box and positively to eject the said shuttle from the said shuttle-box when the latter has reached the proper position therefor, as the lay completes its backward motion, substantially as specified.

33. In a loom, the combination of a lay, a movable shuttle-box pivotally mounted on suitable bearings upon the lay and having a spring-pressed binder pivoted to its rear side and normally pressing inwardly, an inward projection at the top of the shuttle-box adapted to guide the shuttle when moving into the shuttle-box, a stationary shuttle-reservoir properly mounted on the loom-frame and independent of the moving parts of the loom, means operative upon the failure of the filling-thread to move the shuttle-box to the shuttle-reservoir, and means to transfer a shuttle from said reservoir to the shuttle-box as the lay completes its backward motion, substantially as specified.

34. In a loom adapted to renew its supply of filling when necessary, the combination of a shuttle-reservoir and a rocking arm pivoted thereto, a shuttle in said reservoir, and a web-thread from said shuttle to the end of said rocking arm, substantially as shown.

35. In a loom adapted to renew its supply of filling when necessary, the combination of a filling catch or arm pivoted to a stationary part of the loom, a web-carrier, and a web-thread therefrom extending and fastened to said catch or arm and adapted to rock said catch or arm on its axis by the tension of said web-thread, substantially as set forth.

36. In a loom adapted to renew its supply of filling when necessary, a shuttle-reservoir, a filling catch or arm pivotally mounted adjacent to the shuttle-reservoir, means tending to keep the upper end of said arm in a raised position, a shuttle, and a web-thread from the shuttle to the upper end of said catch or arm, substantially as described.

37. In a loom provided with means to supply a fresh shuttle upon failure of the filling-thread, the combination of a lay, a read on said lay, a shuttle having a web-thread whose end is attached to a proper support, a pair of shears pivotally mounted in suitable bearings upon the lay behind the read out of the path of motion of the shuttle and adapted to be operated upon failure of the filling-thread, a web-fork and means intermediate between the web-fork and shears adapted to move the shears blades through the read for the purpose of cutting the said web-thread from the selvage of the cloth as the lay completes its forward motion, substantially as specified.

38. In a loom provided with means to supply a fresh shuttle upon failure of the filling-thread, the combination of a lay, a shuttle movable thereon, a web-fork, a pair of shears mounted in suitable bearings upon the lay out of the path of motion of the shuttle and means intermediate between said web-fork and shears adapted to operate the latter for the purpose of cutting the web-thread projecting from the selvage of the cloth as the lay completes its forward motion, substantially as specified.

39. In a loom provided with means to supply a fresh shuttle upon failure of the filling-thread, the combination of a lay, a pair of shears pivotally mounted thereon in suitable bearings in the rear of the read out of the path of motion of the shuttle, a web-fork, a movable thread-lever mounted on a fixed support, means which tend to elevate the end of said lever, a shuttle having a web-thread whose end is fastened to the upper end of said thread-lever, and means intermediate between the web-fork and the shears adapted to operate said shears upon the failure of the filling for the purpose of cutting the said web extending from the selvage of the cloth as the lay completes its forward motion, substantially as described.

40. In a loom, the combination of a lay and a shuttle-box movable thereon, having a front side, a rear side and one closed outer end, but open at top and bottom and so placed on the lay that when the shuttle-box is in proper operative position the lay itself constitutes the bottom of the shuttle-box, but when the shuttle-box is in proper position for the reception of a fresh shuttle said front side and rear side thereof extend in planes parallel with the top of the lay, substantially as shown.

41. In a loom, the combination of a lay, a shuttle-box having an open bottom, a front side, a rear side and one closed end and provided with carriages on its front side at or below the central longitudinal line thereof, by which carriages it is pivotally connected with the lay, said shuttle-box normally resting with its open bottom upon the lay but rotatable to a position in which its front side and rear side are in planes parallel with the top of the lay, substantially as specified.

42. In a loom, the combination of a lay, a shuttle-reservoir mounted on a fixed support in the rear of the lay independent of the lay, and having an opening in front at the bottom thereof, a vertically-movable shuttle-box mounted pivotally on the lay and having an open bottom, the

edges of which normally rest upon the lay but which open bottom is contiguous to the opening in the reservoir, when the shuttle-box has been rotated a quarter-revolution, means adapted to move a shuttle from said reservoir through the opening in the reservoir and through the open bottom of the shuttle-box, into said shuttle-box and a spring-pressed binder in the shuttle-box to hold said shuttle in position when moved therein, substantially as specified.

43. In a loom, the combination of a lay, a shuttle-receiving pan having an open front and mounted upon a fixed support in the rear of the lay and independent thereof, a vertically-rotatable shuttle-box mounted pivotally on the lay and having an open top and an open bottom, the edges of which bottom normally rest upon the lay, but which open bottom is contiguous to the open front of said pan when the shuttle-box has been rotated a quarter-revolution, and means adapted to positively move a shuttle from said shuttle-box into said receiving-pan when said shuttle-box is raised to the elevated position last aforesaid, substantially as shown.

44. In a loom, the combination of a lay, a shuttle-receiver mounted on a fixed support in the rear of the lay, independent of the lay and having an opening in front at the bottom thereof, a shuttle-receiving pan having an open front and mounted on a fixed support in the rear of the lay and independent thereof, two vertically-rotatable shuttle-boxes mounted pivotally on the lay adjacent, respectively, to said receiver and pan, each of which shuttle-boxes has an open top and an open bottom with the bottom edge normally resting upon the lay but which open bottoms are directed rearwardly when the shuttle-boxes have been rotated a quarter-revolution, means adapted to rotate said shuttle-boxes in unison, mechanism adapted to move a shuttle from said receiver into the contiguous shuttle-box, and mechanism adapted to move a shuttle from the opposite shuttle-box into the contiguous receiving-pan, substantially as specified.

45. In a loom, the combination of a lay, a shuttle-receiver mounted on a fixed support in the rear of the lay, independent of the lay and having an opening in both front and rear at the bottom thereof, a vertically-rotatable shuttle-box pivotally mounted on the lay and having an open top and an open bottom with the bottom edge normally resting upon the lay but which open bottom is directed rearwardly when the shuttle-box has been rotated a quarter-revolution, and a reciprocally-movable pusher adapted and arranged to move a shuttle from said receiver into the shuttle-box, when the shuttle-box is raised to the elevated position last aforesaid, substantially as described.

46. In a loom, the combination of a lay, a shuttle-receiving pan having an open front and mounted upon a fixed support in the rear of the lay and independent of the lay, a vertically-rotatable shuttle-box mounted pivotally on the lay and having an open top and an open bottom with the bottom edge normally resting upon the lay but which open bottom is directed rearwardly when the shuttle-box has been rotated a quarter-revolution and a reciprocally-movable pusher adapted and arranged to move a shuttle from said shuttle-box into said receiving-pan when the shuttle-box is raised to the elevated position last aforesaid, substantially as specified.

47. In a loom, the combination of a lay, a shuttle-receiver mounted on a fixed support in the rear of the lay, independent of the lay and having an opening in front and in the bottom thereof, a shuttle-receiving pan having an open front and mounted on a fixed support in the rear of the lay and independent thereof, two vertically-rotatable shuttle-boxes mounted pivotally on the lay adjacent, respectively, to said receiver and pan, each of which shuttle-boxes has an open top and an open bottom with the bottom edge normally resting upon the lay but which open bottoms are directed rearwardly when the shuttle-boxes have been rotated a quarter-revolution, means adapted to rotate said shuttle-boxes in unison, a reciprocally-movable pusher adapted to move a shuttle from said receiver into a contiguous shuttle-box and a reciprocally-movable pusher adapted to move a shuttle from the opposite shuttle-box, into the contiguous receiving-pan, all operating substantially as shown and for the purpose specified.

48. In a loom having a receptacle for shuttles independent of the lay, the combination therewith of a lay, a shuttle-box pivotally mounted upon the lay upon suitable bearings so as to vertically rotate a quarter-revolution, a gear fastened to the shuttle-box and concentric with the pivotal mounting of said shuttle-box, a gear mounted on a support upon the lay and engaging the first-named gear, and means adapted to rotate the last-named gear, substantially as and for the purpose specified.

49. In a loom, the combination of a lay, a shuttle-receiver having an opening in front at the bottom thereof and mounted on the frame of the loom behind the lay, a shuttle-receiving pan having an open front and mounted on the frame of the loom behind the lay, a rod properly mounted at its ends on the lay and extending longitudinally in front of the lay and parallel thereto, a shuttle-box mounted on said rod through carriages on the lower front edge thereof adjacent to the shuttle-receiver, a shuttle-box mounted on said rod through carriages on the lower front edge thereof adjacent to the shuttle-receiving pan, each shuttle-box having an open

top and an open bottom, a gear fastened in each of said shuttle-boxes and mounted upon said rod, a rock-shaft properly mounted on the lay parallel with said rod, means adapted to rock said shaft, two gears fastened on said rock-shaft and engaging, respectively, with said shuttle-box-gears, a reciprocally-movable pusher adapted and arranged to move a shuttle from said receiver into the contiguous shuttle-box, and a reciprocally-movable pusher adapted and arranged to move a shuttle from the opposite shuttle-box into the contiguous receiving-pan, substantially as specified.

50. In a loom, the combination of a lay, a shuttle-receiver having an opening in front at the bottom thereof and mounted on the loom-frame behind the lay, a shuttle-receiving pan having an open front and mounted on the loom-frame behind the lay, a rod properly mounted at its ends on the lay and extending longitudinally in front of the lay and parallel thereto, a shuttle-box mounted on said rod through carriages on the lower front edge thereof adjacent to the shuttle-receiver, a shuttle-box mounted on said rod through carriages on the lower front edge thereof adjacent to the shuttle-receiving pan, each shuttle-box having an open top and an open bottom, a gear fastened to each of said shuttle-boxes and mounted upon said rod, a rock-shaft properly mounted on the lay parallel with said rod, two gears fastened on said rock-shaft and engaging, respectively, with said shuttle-box gears, a reciprocating pusher arranged and adapted to move a shuttle from the shuttle-receiver into the contiguous shuttle-box, a reciprocating pusher arranged and adapted to move a shuttle from the opposite shuttle-box into the receiving-pan, an oscillating web-fork, and means intermediate between said web-fork and shaft adapted to rock said shaft, substantially as shown.

51. In a loom, the combination of a lay, a shuttle-receiver having an opening in front at the bottom thereof and mounted on the loom-frame behind the lay, a shuttle-receiving pan having an open front and mounted on the loom-frame behind the lay, a rod properly mounted at its ends on the lay and extending longitudinally in front of the lay and parallel thereto, a shuttle-box mounted on said rod through carriages on the lower front edge thereof adjacent to the shuttle-receiver, a shuttle-box mounted on said rod through carriages on the lower front edge thereof adjacent to the shuttle-receiving pan, each shuttle-box having an open top and an open bottom, a gear fastened to each of said shuttle-boxes and mounted upon said rod, a rock-shaft properly mounted upon the lay parallel with said rod, two gears fastened on said rock-shaft and engaging, respectively, with said shuttle-box gears, a reciprocating pusher adapted to move a shuttle from the shuttle-receiver into the contiguous shuttle-box, a reciprocating pusher adapted to move a shuttle from the opposite shuttle-box into the receiving-pan, an oscillating web-fork adapted to take a horizontal position upon the faller of the filling-thread, a sliding plate to which the web-fork is pivoted, a shaft driven by power and provided with a cam, a bent lever pivotally mounted on the loom-frame and having its lower end in contact with said cam and its upper end engageable with said web-fork when the latter is horizontal upon the faller of the filling-thread, a rock-shaft properly mounted and having a lever-arm movable by the sliding plate, a switch-block with a lower groove which is substantially horizontal and with a slot which is angularly inclined upward, a switch pivotally mounted and adapted to close either said groove or slot, a lever-arm on the last-named rock-shaft, a link connection between the last-named lever-arm and said switch, and an arm extending from one of the gears last mentioned and having at its end a friction-roller movable in said groove or slot according to the position of said switch, all combined and operating substantially as shown and for the purpose specified.

52. In a loom, the combination of a lay, a shuttle-receiving pan supported on the loom-frame behind and independent of the lay, a shuttle-box rotatably mounted on said lay and having an open top and an open bottom, means adapted to rotate the shuttle-box a quarter-revolution, a shutter hinged to the shuttle-box in a plane in extension of the top edge of the shuttle-box and extending in the same direction, which shutter in its normal extended position is parallel with the top of the lay but is movable on its hinge to a position at a right angle with its normal plane, means adapted to move said shutter from its normal position to its angular position, a spring adapted to return said shutter to its normal position when free, and means adapted to move a shuttle from the shuttle-box to the receiving-pan, substantially as specified.

53. In a loom, the combination of a lay, a shuttle-receiver supported on the loom-frame behind the lay and independent of it and having a rear opening and a front opening at its bottom and also a rearwardly-extending plate, a shuttle-box rotatably mounted on the lay and having an open top and an open bottom, means adapted to rotate said shuttle-box a quarter-revolution, a pusher supported by said rearwardly-extending plate and adapted to move a shuttle from the shuttle-receiver into the shuttle-box when the shuttle-box is in its elevated position, a lever pivotally mounted on the loom-frame, a link-rod connecting the top of said lever with said pusher, a binder-shaft mounted on and movable with the lay, means adapted to rock said binder-shaft upon the faller of the filling-thread, and a lever-arm from the binder-shaft arranged to come

into contact and to move the first-named lever, when said binder-shaft is rocked as aforesaid, substantially as described.

54. In a loom, the combination of a lay, a shuttle-receiving pan supported on the loom-frame behind the lay and independent of it and having an open front, a shuttle-box rotatably mounted on the lay and having an open top and an open bottom, means adapted to rotate said shuttle-box a quarter-revolution, a pusher in front of said shuttle-box and adapted to move a shuttle from the shuttle-box into the receiving-pan, a binder-shaft mounted on and movable with the lay, means adapted to rock the binder-shaft, a binder-finger fastened on the binder-shaft and extending upwardly, a vertical rock-shaft with suitable supports on the loom-frame, a bent lever fastened to the vertical rock-shaft at the bottom thereof and at a right angle thereto, one of whose ends is in line with the top of the binder-finger and movable thereby when the shuttle-box has been rotated to its elevated position and the other of whose ends has a spring-bearing against the loom-frame, a bent lever-arm fastened at one end to the vertical rock-shaft at the upper end thereof and having its other end slotted, and a sliding rod mounted in suitable ways and connected to the pusher at its front end and at its other end to the slotted end of the last-named lever-arm by means of a headed screw extending from the sliding rod through the slot of said lever-arm, substantially as shown.

55. In a loom, the combination of a lay, a shuttle-receiving pan supported on the loom-frame behind the lay and independent of it and having an open front, a shuttle-box rotatably mounted on the lay and having an open top and an open bottom, means adapted to rotate said shuttle-box a quarter-revolution, a pusher in front of said shuttle-box and adapted to move a shuttle from the shuttle-box into the receiving-pan, a vertical rock-shaft having an angular extension therefrom and a spring, a lever-arm fastened to the top of said vertical rock-shaft and provided with a slotted end, and a sliding rod mounted in suitable ways and connected at its forward end with the pusher and at its rear end to the slotted end of said first-named lever-arm by means of a screw passing therefrom through the slot of said lever, a binder-shaft properly mounted, means adapted to rock said binder-shaft, and an extension from the binder-arm adapted to move the lower angular extension of the vertical rock-shaft when the shuttle-box is in its elevated position, substantially as specified.

56. In a loom, the combination of a lay, a shuttle-receiving pan supported on the loom-frame behind the lay and independent of it and having an open front and an upwardly-extending arm, a shuttle-box rotatably mounted upon the lay and having an open top and an open bottom, means adapted to rotate said shuttle-box a quarter-revolution, a pusher in front of said shuttle-box and adapted to move a shuttle from the shuttle-box into the receiving-pan, a binder-shaft mounted on and movable with the lay, means adapted to rock the binder-shaft, a spring-pressed binder upon the shuttle-box, a binder-finger fastened at its bottom to the binder-shaft and having its upper end in contact with said binder, a lever pivotally mounted on the shuttle-box and having its shorter end located beneath said binder and its longer end extending in the line of the projecting arm of said shuttle-receiving pan when the shuttle-box is in its elevated position, a vertical rock-shaft with suitable supports on the loom-frame, a bent lever fastened to the vertical rock-shaft at the bottom thereof at a right angle thereto, one of whose ends is in line with the top of said binder-finger when the shuttle-box is in its elevated position and the other of whose ends has a spring-bearing against the loom-frame, a bent lever-arm fastened at one end to the top of the vertical rock-shaft and having a slot in its other end, a sliding rod suitably mounted in ways and connected with said pusher at its front end and to the last-named lever-arm at its other end by means of a screw extending therefrom through said slot, substantially as set forth.

57. In a loom, the combination of a lay, a shuttle-receiving pan supported on the loom-frame behind the lay and independent of it, and having an open front, a guide-plate upon the top of said pan, partially covering the same, a rotatably-mounted shuttle-box upon the lay having an open top and an open bottom, means adapted to rotate said shuttle-box a quarter-revolution, mechanism arranged and operative to move a shuttle from the shuttle-box into the receiving-pan when the shuttle-box is in its elevated position, and springs or bars loosely mounted at their upper ends upon said guide-plate and capable of moving freely toward the interior of the receiving-pan but incapable of moving outwardly therefrom, substantially as shown and for the purpose specified.

58. In a loom, the combination of a lay, a breast-beam, a rotatable shaft having a cam thereon, a bent lever mounted on the loom-frame having its lower end in operative contact with said cam, an oscillating web-fork having a hooked end with which the upper end of said bent lever is engageable upon failure of the filling-thread, a sliding plate to which the web-fork is pivoted and which is movable in proper guides, a rock-shaft mounted on said breast-beam, a lever-arm fastened on the rock-shaft and movable by the pressure upon its upper end caused by the sliding of the said plate, a holding-pawl pivoted on the loom-frame, a pressure-arm fast-

ened on said rock-shaft and bearing against the upper end of said holding-pawl, a ratchet-gear with which said holding-pawl is engageable, a feeding-pawl having a counterpoise and pivotally mounted on said bent lever near the fulcrum thereof and having its lower end engageable with said ratchet-gear, a pinion in the same shaft as the ratchet-gear and rotating therewith, a sand-roller having a gear meshing with said pinion, a cloth-roller receiving cloth from the sand-roller, and shuttle-transferring mechanism for removing a spent shuttle and supplying a fresh filled shuttle, the said parts being so arranged and timed in their movements that during the shuttle-transferring operation, the said holding-pawl is disengaged from said ratchet-gear thereby temporarily preventing the winding of the cloth upon the cloth-roller, substantially as specified.

59. In a loom having shuttle-changing mechanism whereby a spent shuttle is removed and a fresh filled shuttle is supplied, the combination therewith of a lay, a pair of shears, one of whose handles is pivoted to a fixed support on the lay, a rocking shaft and means adapted to rock it operative upon failure of the filling-thread, a collar-cam fixed on said shaft and having two diametrically-located deep notches and two diametrically-located shallow notches midway between the first-named notches, a ratchet-cam loosely mounted on said shaft and having two diametrically-arranged radial arms, four ratchet-teeth ninety degrees apart and two diametrically-arranged cam projections engageable with said notches of the collar-cam, a bracket on the lay, a pawl pivotally mounted on the lay and having a downward extension, a ratchet-arm loosely mounted on said shaft beside the ratchet-cam, a spiral spring surrounding said shaft and having one end thereof bearing on the ratchet-arm and the other end bearing against a fixed collar on said shaft, a spring-pressed pawl mounted on the ratchet-arm and engageable with the teeth of the ratchet-cam, a lever-arm mounted on said bracket, a spiral spring from this lever-arm extending to the downward extension of the first-named pawl, a link-bar pivotally connected with said last-named lever-arm at one end and at the other with one of the handles of said shears, a spiral spring fastened to the last-named lever and extending to a fixed support on the loom-frame, a bracket adapted to support the ratchet-arm when the latter is not in operation, and a bumper extending from the breast-beam, all arranged and operating substantially as and for the purpose specified.

60. In a loom having shuttle-changing mechanism whereby a spent shuttle is removed and a fresh filled shuttle is supplied, the combination therewith of a lay, a pair of shears pivotally mounted on the lay, a shuttle-reservoir with shuttles therein, a thread-lever pivoted on a fixed support and having a weighted lower end and an upper end adapted to receive and hold the ends of the web-threads of said shuttles, a shuttle-box adapted to receive a shuttle from said reservoir, a filling-detector, and means intermediate between the filling-detector and shears, operative upon failure of the filling-thread and adapted to close said shears so as to cut the web-thread between the blades thereof which extends from the newly-supplied weaving-shuttle to said thread-lever, substantially as described.

61. In a loom, the combination of a lay, a movable shuttle-box on the lay, a shutter or guide pivotally mounted in suitable bearings at the top near the open end of said shuttle-box above the path of motion of the shuttle and normally extending in a plane therewith, means operative upon failure of the filling to move said shuttle-box and partially rotate the shutter toward the interior of the shuttle-box during the backward movement of the lay and return the same to their normal position during the forward movement of the lay, substantially as described.

696,658. RAILWAY-RAIL JOINT. AXEL A. STROM, Austin, Ill., assignor to Strom Manufacturing Company, Chicago, Ill. Filed Aug. 21, 1901. Serial No. 72,742. (No model.)

Claim.—A rail-joint comprising a bent rail end having at its inner side a recess terminating in a shoulder and having its tread portion beyond this outer side line of the rail cut away, a beveled rail end fitting the recess and having a shouldered end engaging the shoulder of the other rail end, and devices for securing the rail ends together.

696,659. ADJUSTABLE NUT AND PIPE WRENCH. HENRY S. THOMAS, Rahon, N. Y. Filed July 26, 1901. Serial No. 69,512. (No model.)

Claim.—1. A pipe and nut wrench composed of two long compound levers, *a b c* and *y d e*, with notched jaws joined together at *a* and

c, with shoulder-bolts, in combination with two short compound levers, b c and d e, with notched jaws, joined together with shoulder-bolts, the end of one, d e, being formed into a countersunk hook with shoulder-bolt, in combination with lock-out, to engage the same, substantially as shown in Fig. 1, and described.

2. The pipe and nut wrench described, composed of a combination of the four compound levers a b, b c, y d, and d e, having inner notched jaws, one of which, d e, is formed into a countersunk hook to engage a shoulder-bolt having a thumb-out at d, to lock the same, all in combination, and joined together with shoulder-bolts at a b c and d, substantially as shown.

3. A combination in a pipe and nut wrench having four compound jointed levers with roughened inner edges, two long and two short, one of the latter provided with a detachable hook, together with a shoulder-bolt having a shoulder formed to engage a countersunk hook, in combination with a thumb-out threaded thereon, to adjust the same, all in combination, and joined together with shoulder-bolts at the points, a, b, c, and d, substantially as shown and described.

696,660. AUTOMOBILE. WALTER E. TRIVANT, Whitman, Mass.
Filed July 5, 1901. Serial No. 67,096. (No model.)

Claim.—1. In an apparatus of the kind described, a source of gasolene-supply for heating a boiler, a source of water-supply, a pipe connecting the two, means for forcing said water to said gasolene under pressure, an air-dome connected to said water-pipe on the pressure side of said pressure means, and a pressure-regulator for preventing the pressure exceeding a given maximum.

2. In an apparatus of the kind described, a gasolene-tank, a pipe adapted to connect said tank to a boiler, a water-tank, a pipe connecting said water-tank to the gasolene-tank, a pressure-pump for forcing the water under pressure to said gasolene-tank, a pressure-regulator connected with said water-pipe on the pressure side of said pump, and a blow-off connection from said pressure-regulator to the intake side of said pump.

3. In an apparatus of the kind described, a water-tank, a plurality of gasolene-tanks for supplying gasolene for heating a boiler, pipe connections between said several tanks, means for forcing water under pressure to one of said gasolene-tanks either from said water-tank, or from the other gasolene-tank as may be desired.

4. In an apparatus of the kind described, a water-tank, a plurality of gasolene-tanks for supplying gasolene for heating a boiler, pipe connections between said several tanks, and means for forcing water under pressure to either of said gasolene-tanks from said water-tank, or to one of said gasolene-tanks from the other as desired.

5. In an apparatus of the kind described, a water-tank, a plurality of gasolene-tanks for supplying gasolene for heating a boiler, pipe connections between said several tanks, means for forcing water to one of said gasolene-tanks from said water-tank, means for cutting off said water-supply and thereafter withdrawing the water previously forced to said gasolene-tank and forcing the same under pressure to another gasolene-tank.

6. In an apparatus of the kind described, a water-tank, a plurality of gasolene-tanks for supplying gasolene for heating a boiler, pipe connections between said several tanks, a pump for forcing water to one of said gasolene-tanks from said water-tank, means for cutting off said water-supply and thereafter withdrawing the water previously forced to said gasolene-tank and forcing the same under pressure to another gasolene-tank, and a pressure-regulator having a blow-off connection for discharging into either source of water-supply as the case may be.

7. In an apparatus of the kind described, a plurality of tanks adapted to contain either gasolene for heating a boiler or water for communicating pressure to the gasolene, water-pipes connecting said tanks, and a pump for drawing water from one tank and delivering it under pressure to the other tank.

8. In an apparatus of the kind described, a plurality of tanks, adapted to contain either gasolene for heating a boiler or water for communicating pressure to the gasolene, water-pipes connecting said tanks, and a pump for drawing water from either of said tanks and delivering it under pressure to the other tank.

9. In an apparatus of the kind described, a plurality of tanks, one for containing pressure-transmitting fluid and the other for containing gasolene, a gasolene-pipe for delivering gasolene to a boiler, two sets of connecting-pipes between said tanks, said two sets of pipes being connected together and having a pressure-pump interposed therein for transmitting pressure through said pipes, and valves on each side of said two connections for governing the communication of said pressure-pump with one or another of said tanks.

696,661. VEHICLE TIE-REST. LOUIS B. TAYLOR, Thompson, N. Y.
Filed Feb. 26, 1902. Serial No. 66,022. (No model.)

Claim.—1. An auxiliary tie-rest for vehicles, comprising supporting members each member consisting of adjustable sections slidable one upon the other, a tie-rest bar carried by one of said sections, means for securing the said sections in adjusted position and means for detachably securing the auxiliary tie-rest to the permanent tie-rest.

2. An auxiliary tie-rest for vehicles, comprising supporting members, each member consisting of adjustable sections slidable one upon the other, one of said sections being provided with a supporting-foot adapted to rest upon the floor of the vehicle, a tie-rest bar carried by one of said sections, means for securing the said sections in adjusted position, provision for detachably connecting the auxiliary tie-rest to the permanent tie-rest of a vehicle.

3. An auxiliary tie-rest for vehicles comprising supporting members and a tie-rest bar carried by said supporting members, said supporting members being provided at one end with supporting-foot to rest upon the floor of the vehicle and means carried by the opposite ends of said supporting members for ready and detachable engagement with the permanent tie-rest.

4. An auxiliary tie-rest for vehicles comprising supporting members, a tie-rest bar carried by said supporting members, and means for detachably securing the auxiliary tie-rest to the permanent tie-rest, said means

comprising socketed ends carried by the supporting members, the walls of said socketed ends being provided with an opening to permit the passage of the permanent toe-rest into the socketed ends when the free end of said toe-rest is elevated, and to prevent the disengagement of the socketed ends from the permanent toe-rest when the auxiliary toe-rest is in position for use.

3. An auxiliary toe-rest for vehicles comprising supporting members each provided at one end with a foot adapted to rest upon the floor of the vehicle, a toe-rest bar carried by said supporting members, and means for detachably securing the auxiliary toe-rest to the permanent toe-rest, said means comprising socketed ends carried by the supporting members, the walls of said socketed ends being provided with an opening to permit the passage of the permanent toe-rest into the socketed ends when the free end of said toe-rest is elevated and to prevent disengagement of the socketed ends from the permanent toe-rest when the auxiliary toe-rest is in position for use.

6. A toe-rest comprising supporting members, each of said members being formed of sections slidable one upon the other, one of said sections being provided with an elongated slot, a pin carried by the other of said sections and engaging said slot, a set nut engaging said pin, a toe-rest bar carried by one of said sections, and means carried by the other of said sections for detachable connection of the auxiliary toe-rest to the usual permanent toe-rest.

7. A toe-rest comprising supporting members each of said members being formed of sections adjustable with relation to each other, a slot-and-pin connection between said sections, supporting-foot carried by one of said sections, the other of said sections being provided with a socketed end for detachable connection with the permanent toe-rest of a vehicle, said socketed end having a passage-way leading therethrough whereby the auxiliary toe-rest may be engaged with and disengaged from the permanent toe-rest when raised from position of use, and locked to said permanent toe-rest when in position of use.

696,662. SYSTEM OF ELECTRIC LIGHTING AND APPARATUS THEREFOR. FREDERICK LAFITTE, GEORGE VILLARD, and LAURENT PIERRE, Lyons, France. Filed Oct. 6, 1900. Serial No. 28,206. (No Model.)

(Claim.—1. In a system of electric lighting such as described, the combination with an alternating-current generator of high self-induction, of means for passing the current from said generator from one series of lamps to another successively during the intervals existing between the end and the commencement of the half-periods of emission, thereby avoiding sparking, substantially as described.

2. In a system of electric lighting, the combination with a lamp-circuit, of a generator of high self-induction adapted to continuously supply an electric current in the lamp-circuit, and means for adding at predeter-

mined times to the current supplied to the lamp-circuit, the currents of self-induction of the generator.

3. In a system of electric lighting the combination of means for supplying a current to several series of lamps successively during the half-period of the current and means for adding to the current thus supplied the self-induced currents of the coils of the generator; whereby a momentary increase in the potential of the currents reaching the series of lamps in succession will be produced.

4. In a system of electric lighting such as described, the combination with a source of electric current, and a series of lamp-circuits, of a lifting-translator comprising a drum, an electrically conducting-segment thereon, means for rotating said drum and segment, a series of brushes mounted about said drum, and adapted to be engaged successively by said segment and electric connections from said brushes and segment to the lamp-circuits, the whole adapted to shift the current from series to series of the lamp-circuits, successively, and produce a momentary increase in potential of the currents feeding the lamps by utilizing the resulting currents of self-induction, substantially as described.

696,663. ENGINE OR MOTOR. WALTER H. BARKIN, Leytonstone, England. Filed Aug. 2, 1901. Serial No. 70,701. (No Model.)

(Claim.—1. In an engine, the combination with a shaft, of a casing surrounding the same, said casing and shaft being the one revolvable with respect to the other, said casing being provided with plurality of cylinders, pistons in said cylinders provided each with a cam-engaging roller, a cam secured to said shaft and adapted to be engaged by said roller, and means for moving the unactuated pistons, substantially as described.

2. In an engine, the combination with a shaft of a casing surrounding the same, said casing and shaft being the one revolvable with respect to the other, said casing being provided with a plurality of cylinders, pistons in said cylinders provided each with a cam-engaging roller, a cam secured to said shaft and adapted to be engaged by said rollers, and means whereby the actuation of a part of the pistons will give the unactuated pistons the necessary movement to continue the operation of the engine, substantially as described.

3. In an engine, the combination with a shaft, of a casing surrounding the same, said casing and shaft being the one revolvable with respect to the other, a plurality of cylinders secured to said casing, pistons in said cylinders, provided with cam-engaging rollers, a cam secured to said shaft and adapted to be engaged by said rollers and connections between said pistons, substantially as described.

4. In an engine, the combination with a shaft, of a casing surrounding the same, said casing and shaft being the one revolvable with respect to the other, a plurality of cylinders secured to said casing, pistons in said cylinders, provided with cam-engaging rollers, a cam secured to said shaft and adapted to be engaged by said rollers and adjustable connections between said pistons, substantially as described.

5. In an engine or motor the combination of one or more pairs of cylinders, the pistons of which are connected by toggle-links, of a frame to which the cylinders are secured, of a shaft upon which the frame is mounted and of a cam keyed upon the shaft and against which rollers carried by the toggle-links bear, substantially as described.

6. In an engine or motor the combination of one or more pairs of cylinders, the pistons of which are connected by toggle-links carrying rollers, of a frame to which the cylinders are secured, of a fixed shaft upon which the frame is rotatably mounted and of a cam against which the aforementioned rollers bear, substantially as hereinbefore described.

7. In an engine or motor the combination of one or more pairs of cylinders, the pistons of which are connected by toggle-links, of a frame to which the cylinders are secured, of a shaft upon which the frame is mounted, of a cam keyed upon the shaft and against which rollers carried by the toggle-links bear, and of a distributing valve in connection with the shaft for the steam or explosive charge, substantially as described.

8. In an engine or motor the combination of one or more pairs of cylinders, the pistons of which are connected by toggle-links, of a frame to which the cylinders are secured, of a shaft upon which the frame is mounted, of a cam keyed upon the shaft and against which rollers carried by the toggle-links bear, of a casing enclosing the cylinders and having an inlet and outlet for cooling fluid and of vanes in connection with the rotating shaft or cylinders for circulating the cooling fluid, substantially as described.

9. In an engine or motor the combination of one or more pairs of cylinders, the pistons of which are connected by toggle-links carrying rollers, of a frame to which the cylinders are secured, of a shaft upon which the frame is rotatably mounted and of a cam against which the aforementioned rollers bear and of means for adjusting the length of the toggle-links, substantially as described.

10. In an engine, the combination with a casing provided with a pair of oppositely-disposed cylinders, pistons in said cylinders each provided with a cam-engaging roller, a cam adapted to be engaged by said rollers, connections between said pistons, and cam-engaging rollers carried by said connections, substantially as described.

11. In an engine, the combination with a shaft and a casing surrounding said shaft, a pair of cylinders secured to said casing, pistons in said cylinders each provided with a cam-engaging roller, a cam secured to said shaft and adapted to be engaged by said rollers, toggle-levers connecting said pistons and cam-engaging rollers carried by said toggle-levers, substantially as described.

696,664. STOVE. ARTHUR K. BUCKWIRE, Dowagiac, Mich. Filed Nov. 2, 1901. Serial No. 89,968. (No model.)

Claim.—1. The combination with a stove of a downwardly depending socket A' in the top thereof with internal screw-threads formed therein; a downdraft-tube with screw-threads engaging the same whereby it is readily adjusted up and down; and a notch for the engagement of the poker or other suitable device in the top of said downdraft-tube whereby it is readily adjusted up and down; and a damper B above the said socket with connections C therefrom with the outside of the stove whereby the downdraft can be readily controlled.

2. The combination with a stove of a downwardly depending socket A' in the top thereof with internal screw-threads formed therein; a downdraft-tube with screw-threads engaging the same whereby it is readily adjusted up and down; and a damper B above the said socket whereby the downdraft can be readily controlled.

696,665. WIRE-INSULATOR. WILLIAM C. BUNOW, Columbus, Ohio, assignor to the Bunow Company, Columbus, Ohio, a Corporation of Ohio. Filed Jan. 4, 1901. Renewed Sept. 9, 1901. Serial No. 74,788. (No model.)

Claim.—In a wire-insulator, the combination with a pin 6 having a reduced extension 7, said extension being provided with a projecting locking-leg 7, of an insulator-body 1 having a central opening therethrough adapted to receive said pin extension 7 and an internal keyway 4 communicating with said central opening and an inclined bore or extension 5 on the outer end of said insulator, substantially as specified.

696,666. HORIZONTAL PADDLE-WHEEL FOR PROPELLING SHIPS. VICTOR BUNA, Als, Russia. Filed Nov. 20, 1901. Serial No. 89,961. (No model.)

Claim.—1. A horizontal paddle-wheel propelling device for ships and boats, comprising a horizontal paddle-wheel having a plurality of paddle-arms each provided with a paddle-blade, a casing approximately enclosing one-half of said paddle-wheel, and passages at the forward and rearward ends of said casing adapted to direct the flow of the water sucked in at the forward end and expelled at the rearward end of said casing by said paddle-wheel, whereby the rotation of the portion of the paddle-wheel within said casing is utilized in the propulsion of the ship, substantially as set forth.

2. In a horizontal paddle-wheel propelling device for ships and boats, the combination of horizontal paddle-wheels arranged in pairs beneath the bottom of the ship, a shaft projecting through the bottom of the ship from the center of each paddle-wheel and adapted to be driven around by suitable means, a casing beneath the bottom of the ship approximately enclosing the half nearest the center line of the ship of each of said paddle-wheels, an opening into said casing near the forward end of the ship, passages from said opening communicating with the forward end of the casing surrounding each paddle-wheel in such manner that the rotation of the paddle-wheels within said casings may draw in water, through said passages from the forward end of the ship, and passages near the rear end of each paddle-wheel casing adapted to direct the water driven by said paddle-wheels within said casings toward the stern of the ship, whereby the rotation of the portions of the paddle-wheels within said casings is utilized in the propulsion of the ship, substantially as set forth.

3. A horizontal paddle-wheel propelling device for ships and boats, comprising horizontal paddle-wheels arranged in pairs at each side of the center line of the ship, shafts projecting from the center of said paddle-wheels through the bottom of the ship and adapted to be driven around by suitable means, a casing approximately enclosing the half nearest the center line of the ship of each of said paddle-wheels, and passages in said casing whereby the rotation of the paddle-wheels within their casings is utilized to suck in water from the forward end of said casing and to expel water at the rear end of said casing, substantially as set forth.

696,667. TILTING-CHAIR. JOHN HALLINGER, Port Washington, Wis. Filed June 20, 1901. Serial No. 89,986. (No model.)

Claim.—1. In a tilting-chair, a support having upwardly-projecting expanding radial arms provided with terminal fingers and an intermediate space, a chair-seat spider pivoted on the support tiltable backwardly, steps fixed on the spider projecting into the space between said fingers and adapted to engage said fingers toward front and rear and limit the tilting movement of the spider and springs connected to the spider and to the support adapted to hold the spider yieldingly against the front fingers and permit it to tilt to and against the rear fingers on said arms.

2. In a tilting-chair, a support having upwardly-projecting radial arms, a horizontally-disposed chair-seat spider provided with medial downwardly-projecting ears pivoted near their lower extremities on the arms of the support, springs at the rear of the vertical plane of the axis of the pivot, a plate on the spider at the rear of the vertical plane of the pivot against which the front ends of the springs bear, a plate against the rear ends of the springs, a coil secured to the rear spring-plate and passing movably through the front spring-plate, a yoke transverse on the arms

of the support, and a nut turning by screw-thread on said rod and bearing on the yoke at the rear of the axis of the transverse.

3. In a tilting-chair, a support having upwardly-projecting radial arms, a horizontally-disposed chair-seat spider provided with medial downwardly-projecting ears pivoted near their lower extremities on the support, springs at the rear of the vertical plane of the axis of the pivot, a plate on the spider at the rear of the vertical plane of the pivot against which the front ends of the springs bear, a plate against the rear ends of the springs, a rod secured to the rear spring-plate and passing movably through the front spring-plate, a yoke through which said rod passes movably, said yoke having forwardly-extending cranked arms provided with transverse, transverse-bearing members extending inwardly from the upper ends of said arms of the support, and a nut turning by screw-thread on said rod against the yoke at the rear of its transverse.

4. In a tilting-chair device, a spider provided with transverse-sockets extending vertically and open upwardly in its side rails, and steps on the spider near the sockets and a spring-plate provided with transverse adapted to enter and bear in said sockets, and lugs on said plate adapted when the plate is in place having its width in vertical position to engage the steps on the spider and prevent the removal of the plate from the spider while in such normal vertical position.

5. In a tilting-chair, a support having upwardly-projecting arms provided at the front near their upper ends with inwardly-projecting transverse-bearing members having bearings for transverse, a yoke provided with forwardly-projecting cranked arms having transverse-terminals receivable in said transverse-bearings, a spider pivoted on said support, springs mounted on the spider at the rear of its pivot, a spring-controlling rod extending movably through said yoke, and a nut turning on said rod and bearing against said yoke at the rear of the axis of its transverse.

696,668. BEAN-HARVESTER. CLYDE C. FAY, Pettorville, Mich. Filed Jan. 26, 1900. Renewed Feb. 20, 1902. Serial No. 90,000. (No model.)

Claim.—1. In a bean-harvester, the combination with the frame and transporting-wheels, of the inclined rearwardly-converging knives, the rake disposed at the rear of said converging knives, a shaft extending longitudinally of the frame, the ends of the tines of said rake bent partly around said shaft from the under side and threaded, plates through which the tines pass, said plates lying across the upper face of said shaft and receiving the threaded ends of the tines in the rear thereof, nuts screwed onto the threaded ends against said plates, a transverse bar at the rear of the machine common to all of said tines and through which said tines pass, bolts connected with the shaft and secured at their outer ends to said bar and means for raising and lowering said bar to actuate the tines in unison.

2. In a bean-harvester, the combination of the frame and transporting-wheels, the rearwardly-converging knives, the rake disposed at the discharge end of said knives, a shaft journaled in the frame, the tines of said rake clamped to said shaft, a movable cross-bar having apertures therethrough and extending longitudinally of the frame, said bar being common to all of the rake-tines which pass freely through the apertures in said bar, bolts journaled to said shaft and secured at their outer ends to said bar, a rock-shaft journaled at the rear of the frame having an upwardly-projecting crank formed therein and having an integral end portion bent outwardly at right angles to said crank passing freely through said bar and adapted to slide therein.

696,669. BALLING-MACHINE. WILLIAM FLEMING, Chicago, Ill. Filed May 31, 1901. Serial No. 92,600. (No model.)

Claim.—1. In a balling-machine, the combination of a spindle for holding the ball and winding the strand, means for operating said winding means, means for changing the inclination of the spindle during the

winding of the strand, means for temporarily arresting the action of said spindle-inclining means and means for releasing said arresting means by the expansion of the ball, substantially as set forth.

2. In a balling-machine, the combination of a ball pin or spindle, a movable support therefor, whereby the angle of the pin with relation to the strand may be changed, winding means, a cam movable bodily with said support, a rest for said cam, means for rotating said cam, means for arresting the rotation of said cam at a certain period, means adapted to be actuated by the ball for releasing said cam, and thereby permitting a further movement of said pin-support, and means actuated by said further movement of the pin-support for throwing the winding means out of action, substantially as set forth.

3. In a balling-machine, the combination of a pin or spindle, a pivoted gravitating support or frame therefor, winding means, a cam movable bodily with said support, a stationary rest for said cam, means for rotating said cam, means for arresting the rotation of said cam at a certain period, means adapted to be actuated by the ball for releasing said cam and thereby permitting a further movement of said pin-support, and means actuated by said further movement of the pin-support for throwing the winding means out of action, substantially as set forth.

4. In a balling-machine, the combination of a ball pin or spindle, a movable support or frame therefor, winding means, an irregular cam for supporting said frame, revolving in unison with said winding means and being also movable independently thereof, means for arresting said independent movement of the cam, and means for releasing said cam from said arresting means by the expansion of the ball, substantially as set forth.

5. In a balling-machine, the combination of a ball pin or spindle, a movable support or frame therefor, winding means, a gravitating cam for supporting said frame, revolving in unison with said winding means, and being also movable independently thereof, means for arresting said independent movement of the cam, and means for releasing said cam from said arresting means by expansion of the ball, substantially as set forth.

6. In a balling-machine, the combination of a ball pin or spindle, a movable support or frame therefor, winding means, a cam for supporting said frame, revolving in unison with said winding means and being also movable independently thereof, a catch on said cam, and a stop on said pin-frame for arresting said independent movement of the cam, and means for releasing said catch and stop by the expansion of the ball, substantially as set forth.

7. In a balling-machine, the combination of a ball pin or spindle, a movable support or frame therefor, winding means, a cam for supporting said frame revolving in unison with said winding means, and being also movable independently thereof, a flexible catch on said cam, and a stop on said pin-frame for arresting the independent movement of said cam, and means for releasing said stop and catch by the expansion of the ball, substantially as set forth.

8. In a balling-machine, the combination of a ball pin or spindle, a movable support or frame therefor, winding means, a cam for supporting said frame, revolving in unison with said winding means and being also movable independently thereof, a catch on said cam, having a flange

roller, 57, and a stop on said frame for engaging with said roller and arresting the independent movement of said cam, and means for releasing said roller and stop by the expansion of the ball, substantially as set forth.

9. In a balling-machine, the combination of a ball pin or spindle, a movable support or frame therefor, winding means, a cam for supporting said frame, revolving in unison with said winding means and being also movable independently thereof, a catch on said cam, a stop on said frame for engaging with said catch and arresting the independent movement of said cam, and a trip actuated by the expansion of the ball for releasing said stop and catch, substantially as set forth.

10. In a balling-machine, the combination of a ball pin or spindle, a movable support or frame therefor, winding means, a cam for supporting said frame, revolving in unison with said winding means and being also movable independently thereof, a catch on said cam, a stop on said frame for engaging with said catch and arresting the independent movement of said cam, and a trip carried by said pin-frame and actuated by the expansion of the ball for releasing said stop and catch, substantially as set forth.

11. In a balling-machine, the combination of a ball pin or spindle, a movable support or frame therefor, winding means, a cam for supporting said frame, revolving in unison with said winding means and being also movable independently thereof, a catch on said cam, a stop on said pin-frame for engaging with said catch and arresting the independent movement of said cam, an adjustable lag on said catch, and a trip arranged to be actuated by the expansion of the ball for engaging said lag and releasing said catch and stop, substantially as set forth.

12. In a balling-machine, the combination of a ball pin or spindle, a movable pin-frame therefor, winding means, a cam for supporting said frame, revolving in unison with said winding means and being also movable independently thereof, means for detachably connecting said cam operatively with said winding means, and means for releasing said detachable means automatically by the rotation of the cam for permitting the independent movement of the cam, substantially as set forth.

13. In a balling-machine, the combination of a ball pin or spindle, a movable pin-frame therefor, winding means, a cam for supporting said frame, revolving in unison with said winding means, and being also movable independently thereof, means for detachably connecting said cam operatively with said winding means, means for releasing said detachable means for permitting the independent movement of said cam, a stop for arresting said independent movement of the cam, and means for releasing said stop by the expansion of the ball, substantially as set forth.

14. In a balling-machine, the combination of a ball pin or spindle, a movable frame therefor, winding means, a cam for supporting said frame, adapted to revolve in unison with said winding means, and being also movable independently thereof, means for detachably connecting said cam operatively with said winding means, means for releasing said detachable means for permitting the independent movement of said cam, a stop for arresting said independent movement of the cam, means for releasing said stop by the expansion of the ball and permitting said pin-frame to drop and means actuated by the falling of the pin-frame for throwing said winding means out of action, substantially as set forth.

15. In a balling-machine, the combination of a ball pin or spindle, a movable frame therefor, winding means, a cam for supporting said frame, adapted to revolve in unison with said winding means, and being also movable independently thereof, a spring-actuated dog for detachably connecting said cam operatively with said winding means, and means for releasing said dog, actuated by the motion of the cam, substantially as set forth.

16. In a balling-machine, the combination of a ball pin or spindle, a movable frame therefor, winding means, a cam for supporting said frame, adapted to revolve in unison with said winding means and being also movable independently thereof, a spring-actuated dog, for detachably connecting said cam operatively with said winding means, and the cam, 42, fixed with relation to said first cam for releasing said dog as said first cam revolves, substantially as set forth.

17. In a balling-machine, the combination of a ball pin or spindle, a movable frame therefor, winding means, a cam for supporting said frame, having a hub rotatable independently thereof and on which said cam is journaled, a spring-actuated lever secured to said cam, a dog connected with said lever for locking said hub and cam together, and a cam, 42, interposed in the line of movement of said lever for engaging the same and disengaging said dog from said hub, substantially as set forth.

18. In a balling-machine, the combination of a ball pin or spindle, a movable frame therefor, winding means, a cam for supporting said frame, a hub on which said cam is journaled, revolving in unison with said winding means, means for detachably connecting said hub and cam together, and cam, 41, for disengaging the last said means, and having the depression, 43, in which the last said means settles, for holding the last said cam and hub disengaged, substantially as set forth.

19. In a balling-machine, the combination of a ball pin or spindle, a

movable frame therefor, winding means, a cam for supporting said frame, a cam-shaft for said cam operatively connected with said winding means and provided with a clutch member, a second clutch member detachably secured to said cam, means for automatically detaching said cam from said second clutch member as the cam-shaft revolves, means for limiting the independent movement of said cam, and means for disengaging said clutch members at will, substantially as set forth.

20. In a balling-machine, the combination of a ball pin or spindle, a movable frame therefor, winding means, a cam for supporting said frame, movable independently of said winding means, a cam-shaft for said cam operatively connected with said winding means, a clutch member secured thereto, a second clutch member detachably connected to said cam, a second cam fixed to said frame, means carried by said first cam for engaging said second cam and releasing the first cam from said clutch member, means for limiting the independent movement of said first cam, and means for disengaging said clutch members at will, substantially as set forth.

21. In a balling-machine, the combination of a ball pin or spindle, a movable frame therefor, winding means, a cam for supporting said frame, a cam-shaft for said cam operatively connected with said winding means, a clutch member on said cam-shaft, a second clutch member, a spring-actuated dog for securing said second clutch member to said cam, means for holding said dog released as the cam-shaft revolves, a disengageable stop for holding said cam against independent movement when said dog is released, means for releasing said stop by the expansion of the ball, and means for releasing said clutch members at will, substantially as set forth.

22. In a balling-machine, the combination of means for forming the ball, means for driving said ball-forming means, a power-transmitting device for imparting motion to the last said means, a shifter for throwing said power-transmitting device out of action, a latch for holding said shifter inactive, a revolving trip for releasing said latch, a gear for actuating said trip, and means operatively related to and adapted to be actuated by the expansion of the ball for shifting said gear into operative connection with said driving means, substantially as set forth.

23. In a balling-machine, the combination of means for forming the ball, means for driving said ball-forming means, a power-transmitting device for imparting motion to said driving means, a shifter for throwing said device out of action, a latch for holding said shifter inactive, two gears normally out of action, one connected with said driving means and the other with said trip, and means for shifting said gears into engagement by the expansion of the ball, substantially as set forth.

24. In a balling-machine, the combination of means for forming the ball, means for driving said ball-forming means, as helical, means for supporting said helical against downward movement, means for releasing said supporting means by the expansion of the ball, a power-transmitting device for imparting motion to said driving means, a shifter for throwing said device out of action, a latch for holding said shifter against movement, a revolving trip for releasing said latch, a shaft for operating said trip, a gear for operating said shaft slidable longitudinally thereof, the roller, 50, arranged to be struck by said helical when it falls, means operatively connecting said roller with said gear for shifting it lengthwise of said shaft, a companion gear, and means connecting said companion gear with said driving means for imparting motion to said first gear when the latter is shifted, substantially as set forth.

25. In a balling-machine, the combination of a speed for the yarn, means for forming the ball, means for driving said ball-forming means detachably related thereto, tension devices arranged to bear against the yarn on the speed, and means for disengaging said driving means and ball-forming means by the motion of said tension devices toward the speed, substantially as set forth.

26. In a balling-machine, the combination of a speed for the yarn, means for forming the ball, driving means therefor, means for disengaging said driving means from said ball-forming means, a tension device adapted to bear against the yarn on the speed, a spring for holding said tension device against the speed, an adjustable arm connected to said tension device, a latch for holding out of action the said means for disengaging the driving means and ball-forming means, arranged over, and adapted to be released by said adjustable arm, as the tension device approaches the speed, substantially as set forth.

696,670. SPARKING FLUG. HENRY C. POLMER, HARRY MORSE, and EDWARD R. JACOBSON, West Sumnerville, Mass.; said Jacobson assignor to said Polmer and Morarty. Filed Dec. 14, 1899. Serial No. 49,393. (No model.)

Claim.—1. In a device of the kind described, containing two spark electrodes and conductors leading thereto approximately parallel, as to

relation between said conductors consisting of two contiguous parts composed of refractory insulating material, one part being mounted in close contact around one of said conductors, and the other surrounding the former, one of said parts extending integrally lengthwise of the device, and the other of said parts being made up of a series of layers extending radially of said lengthwise part, and means holding said insulation under longitudinal compression.

2. In a device of the kind described, comprising a central conductor or core, a tubular insulation closely embracing said core and without transverse aperture or joint throughout its length, and a surrounding insulation mounted on said tubular insulation and composed of a series of disks extending transversely of said tubular insulation and compressed tightly together thereon, both of said insulations being composed of refractory material, and a second conductor mounted outside of said insulation, said two conductors being provided at one end with spark-electrodes.

3. A device of the kind described, comprising two electrodes, a casing carrying one, and a core carrying the other, combined with insulation filling the space between said core and casing, and comprising longitudinal and transverse layers of refractory insulating material compressed together, each layer being transversely integral and impervious throughout its area.

4. A device of the kind described, comprising two spark-electrodes, a central conductor for one, a concentric casing for the other, insulation filling the space between said casing and conductor composed of a tubular part closely surrounding said central conductor and transversely impervious throughout its area, and a series of disks compressed about said tubular insulation, and each extending radially thereto, said disks and tubular part being composed of refractory material, the peripheral surface of said compressed disks containing a central rib against which said casing abuts on one side, a collar adjustably secured to said casing and abutting against said rib on the opposite side, and means for holding said insulation under longitudinal pressure.

696,671. KINGS FOR FURNITURE. EDGAR A. GAY, Rochester, N. Y., assignor to the King Company, Chicago, Ill., a Corporation of Illinois. Filed Oct. 19, 1891. Serial No. 73,392. (No model.)

Claim.—1. In a hinge, the combination, of two members, a rack on one of the members, a pawl on the other member engaging the rack to support said members in adjusted position when moved outwardly, a supporting-surface on the first member, and a carrier adapted to slide on the said supporting-surface and attached to the pawl to support the latter out of engagement with the rack when said pawl is moved inwardly.

2. In a hinge, the combination, of two members, a rack on one of the members, and a pawl carried by the other member and adapted to engage the rack, a supporting-surface on the first-mentioned member, a carrier adapted to slide thereon and pivotally connected to the pawl, and means for raising the latter out of engagement with the rack, whereby the carrier is permitted to fall to an operative position for supporting the pawl on the said supporting-surface.

3. In a hinge, the combination, of two members, a rack at one side of one of said members, said rack having a supporting-surface, a pawl carried by the other member and engaging the rack, a carrier adapted to slide on the supporting-surface and pivotally connected to the pawl, and means for elevating the pawl when at the end of the rack, whereby the said carrier is caused to assume a position with relation to the supporting-surface to cause said carrier to support the pawl out of engagement with said rack.

4. In a hinge, the combination, of two members, a rack and a supporting-surface on one of said members, a pawl carried by the other member and normally engaging the rack, a stop adapted to be engaged by the pawl for limiting the operation of the said members, a carrier on the pawl, and means for causing said carrier to move beneath the pawl and engage the supporting-surface for the support of the pawl when the latter engages said stop.

5. In a hinge, the combination, of two members, a rack and a supporting-surface on one of the members, a pawl having an inclined face and pivoted to the other member and adapted to engage the rack, a carrier pivoted on the pawl, and a stop adapted to be engaged by the inclined face of the pawl whereby the pawl is limited in its movement and

elevated out of engagement with the rack and said carrier permitted to fall to the supporting-surface and thereby support said pawl.

6. In a hinge, the combination, with a member having a rack extending in substantially horizontal position, a second member pivoted to the first, of a pawl pivoted on the second member below the pivotal joint of said members and adapted to be drawn across the said rack when the members are separated, means operating to elevate the pawl out of engagement with the rack, and a carrier for supporting the pawl out of operative position when said members approach each other.

7. In a hinge, the combination, with a member having the outwardly-curved lower portion forming a supporting-surface and having the rack, of a second member, a pawl thereon the free end of which is adapted to engage the rack when said member is moved in one direction, and the carrier pivoted to the pawl and adapted to move on the supporting-surface out of operative position to support the pawl and to engage the supporting-surface and support the pawl out of engagement with the rack when the pawl is moved with its member in the opposite direction.

8. In a hinge, the combination, of two members, one having a rack, and a pawl pivoted to the other member and adapted to engage the rack, a part pivoted to the pawl and adapted to slide in an operative position on the member carrying the rack, a stop on said member, and a projection on the pawl engaging the stop, whereby the pawl is lifted out of engagement with the rack and the said pawl pivoted part allowed to pass into operative position, whereby the pawl will be supported and the hinge members allowed to close.

9. In a hinge, the combination, of two members, one of said members having a guide and a rack, a pawl on the other member coacting with said rack, a carrier pivoted to the pawl and adapted to support the latter out of engagement with the rack when said carrier and pawl are moving in one direction, said carrier having the elongated base coacting as specified with the guide.

10. In a hinge, the combination, of two members, one having a rack and a support, a pawl mounted on the other member, adapted to engage the rack and having an inclined surface, a stop on the first member adapted to be engaged by said inclined surface of the pawl and to limit the operation of the members and raise the pawl out of engagement with the rack, and means between the support and pawl adapted to coast with the two when the pawl is raised to hold the latter out of operative position when moving across the rack in one direction.

11. In a hinge, the combination, of two members, one having a rack and a support, a pawl on the other member adapted to engage the rack, said pawl having an inclined surface, a stop on the first member adapted to be engaged by said inclined surface of the pawl, to elevate the latter out of engagement with the rack, and having a projection extending over the face of the pawl to limit its pivotal movement, and means between the support and pawl actuated by the engagement of the latter with the stop to hold the pawl out of operative position when it is being returned across the rack.

12. In a hinge, the combination, of two members, one of said members having a rack and a supporting-surface, and the other provided with a pawl having an inclined surface, a stop on the first-mentioned member arranged in the path of and adapted to be engaged by said inclined surface of the pawl and to elevate the latter out of engagement with the outer end of the rack, a carrier pivoted on the pawl and having a bearing-surface extending toward the inner end of the rack in advance of its pivotal point and adapted to engage the supporting-surface of the opposite member when the pawl is elevated and to move over the same.

13. In a hinge, the combination, of opposite pivoted members, a rack adjacent to one of the same, a pawl pivoted to the other of said members and adapted to engage the rack when said pawl is moved in one direction, and means for permitting the engagement of the pawl at any point of the rack when said pawl and its carrying member is moved first in the disengaging direction and subsequently in an opposite or engaging direction.

14. In a hinge, the combination, of opposite pivoted leaves or members, a pawl connected loosely to one of the same, a pawl-engaging device located on the companion member or leaf and adapted to engage said pawl for the purpose of giving intermediate adjustments in said leaves or members, and means operated by the members for causing said pawl and engaging device to cooperate or engage at any of said intermediate adjustments without the necessity of operating the said hinge members to their limit of adjustment.

696,672. PAPER-HANGING MACHINE. JULIUS H. GILMERMAN, Cleveland, Ohio. Filed Feb. 2, 1898. Serial No. 60,398. (No model.)

Claim.—1. A wall-paper-hanging machine consisting of side plates D D, a supporting cross-bar D', a removable rotatable paste-brush E, journaled in slots e e' on the sides of said plates D D, a removable paste-box F suspended on the journals of the paste-brush, a movable cross-bar J playing in slots j j' in the side plates D D, a brush L carried by said cross-

bar J, arms *g g* pivoted to the sides D D carrying paper-roll holder, a permanent brush N attached to lower corners of plates D D, levers K K fulcrumed on the sides of the plates D D, links O O' connecting said levers with the sliding brush-holders *e e'*, the links P P' connecting the levers N N' with the sliding brush-holding cross-bar J, a knife Z on said sliding cross-bar, and a slotted cross-bar Y on upper corners of the plates D D, all constructed and combined to operate substantially as and for the purpose set forth.

2. The wall-paper-hanging machine comprising the side supporting-plates D D supported on the cross-bar J, a removable and rotatable paste-brush E, journaled in slides *e e'* on the plates D D, a removable paste-box F suspended on the journals of the brush E, a movable cross-bar J playing in slots *j j* in the side plates D D, a brush L carried by said cross-bar J, arms *g g* pivoted to the sides D D carrying paper-roll holder, a permanent brush M attached to lower corners of the plates D D, levers N N' fulcrumed on the side plates D D, links O O' connecting said levers with the sliding brush-holders *e e'*, the links P P' connecting the levers N N' with the sliding brush-holding cross-bar J, a knife Z on said sliding cross-bar J, and a slotted cross-bar Y on the upper corners of the plates D D, in combination with the upright adjustable slotted tracks A A, frame W on pieces *a a* of the uprights, shaft E supported in said frame, grooved wheels V V on the ends of said shaft, bevel-pinion T on said shaft, a bevel-gear X journaled in the frame W and provided with a hand-crank ropes *r r* attached to said wheels V V and passing up over pulleys *t t* at the top of frame A A thence down and attached to the ends of cross-bar J, and the vertical chain U attached to top and bottom of frame A A, and the sprocket-wheel U' on the paste-brush shaft meshing with said chain, all constructed and combined to operate substantially as and for the purpose set forth.

696,678. FREDERICK COLLIER-MILLER. HENRY SCHWENDE and JOHN E. DEANBOLT, Ontario, Wis. Filed Dec. 18, 1900. Serial No. 42,300. (No model.)

Claim.—1. The combination, in a roller-mill, of a vibrating shoe, a vertically-movable power-shaft, connections between the latter and said shoe to vibrate said shoe, a grinding-roll, friction-wheels on said power-shaft to engage said grinding-roll, tension arms or levers having bearings for said vertically-movable power-shaft, a shaft having eccentrics connected to and supporting said tension-levers, at one end thereof, and springs to depress said tension-levers, for the purpose set forth, substantially as described.

2. The combination, in a roller-mill, of a vibrating shoe, a vertically-movable power-shaft, connections between the latter and said shoe to vibrate said shoe, a grinding-roll, friction-wheels on said power-shaft to en-

gage said grinding-roll, tension-levers having bearings for said vertically-movable power-shaft, a movable grinding-roll, adjusting-arms having bearings therefor and a shaft in fixed bearings having eccentrics connected to said tension-levers and said adjusting-arms whereby said vertically-movable power-shaft and said movable grinding-roll are adjusted simultaneously, substantially as described.

696,674. CHECK-HOOK. EDWIN HARRISON and JOSEPH A. PLATT. Edred, Pa. Filed Apr. 21, 1901. Serial No. 54,888. (No model.)

Claim.—The combination with a checkrein-hook having its upper end twisted to present the end in a vertical plane, and formed with opposite shoulders, of a loop comprising spring-arms reduced to conform to said shoulders embracing the vertically-disposed end of the hook and pivotally secured thereto, and formed adjacent to their pivotal point with openings; and bosses projecting from opposite sides of the upper end of the hook below the pivotal point of the loop over which the spring-arms snap to engage the bosses in the openings of the loop.

696,675. PISTON-VALVE. WILLIAM HESTON, Homestead, Pa. Filed Apr. 22, 1901. Serial No. 54,977. (No model.)

Claim.—1. The combination of a piston comprising a head *a*, in which is an external annular groove, and two stems *d d'*, cones embrace-

ing and movable upon said stems with their small ends pointing toward the head, internally-tapered split sleeves embracing said cones with their thick ends toward and in contact with said head, expandible packing-rings embracing said split sleeves, and means for forcing said cones toward said head into said split sleeves, substantially as and for the purpose specified.

2. The combination of a piston comprising a head *a*, in which is an annular groove, and two stems *a'* *a''*, cones embracing and movable upon said stems with their small ends pointing toward the head, internally-tapered split sleeves embracing said cones with their thick ends toward and in contact with said head, expandible packing-rings embracing said split sleeves, springs engaging with the large ends of said cones, caps which engage with said compress said springs, and clamp said packing-rings, and means for holding down said caps, substantially as and for the purpose specified.

696,676. GATE. THOMAS A. HILL, Knoxville, Tenn. Filed June 6, 1901. Serial No. 65,204. (No model.)

Claim.—1. A gate supported on a horizontal hinge and having a counterbalance-chest comprising two compartments which are at opposite sides of a plane cutting said gate lengthwise and near which said hinge lies, substantially as described.

2. A gate supported on a horizontal hinge and a counterbalance-chest comprising two compartments which are at opposite sides of a plane cutting said gate lengthwise and near which said hinge lies, each such compartment having an aperture and removable means for closing said aperture, substantially as described.

3. A gate having a detachable counterbalance-chest and braces, *C*, extending from the sides of said chest to the top rail of the gate and having holes for receiving a hinge-shaft, *C'*, between the point of attachment to said chest and the point of attachment to the frame of the gate, substantially as described.

4. A counterbalance-chest for a gate, said chest being provided at its upper portion and at its lower portion with means for detachably securing horizontal bars, substantially as described.

5. A counterbalance-chest for a gate, said chest being provided at its upper portion and at its lower portion with means for detachably securing horizontal bars, and braces leading from the sides of said chest toward the free end of the gate, substantially as described.

6. A gate having a top rail and a bottom rail extending, respectively, over and beneath a hinge, and a counterbalance-chest located between and detachably secured to said rails, substantially as described.

7. A counterbalance-chest substantially upright when the gate is in its closed position, a horizontal partition dividing said chest into two compartments, and suitable apertures for the insertion of weight material into said compartments, substantially as described.

8. A counterbalance-chest for a gate, said chest comprising side walls, top and bottom walls, and front and rear walls, the latter having extensions for the attachment of said chest to the gate, substantially as described.

9. The combination with two pairs of converging posts, of a gate hinged to two of said posts standing at opposite sides of said gate, a shaft, *d*, supported by the posts at one side of said gate, and an arm, *H*, secured to said shaft by a hinge permitting horizontal movement of said arm, substantially as described.

10. The combination with two pairs of converging posts, of a gate hinged to two of said posts standing at opposite sides of said gate, and a cord-supporting arm hinged to said posts above said gate to move in a horizontal plane, substantially as described.

696,677. APPARATUS FOR CURING TOBACCO. GEORGE F. HILLMAN, Florence, Mass. Filed Nov. 11, 1901. Serial No. 61,798. (No model.)

Claim.—1. In an apparatus for curing tobacco, the combination with a pipe having an upwardly-directed bend terminating within the tobacco-chest, and provided at said bend with a hood extended outwardly beyond the diameter of the pipe, and having an inverted cone dependent into the opening in the pipe, of a furnace having a hot-air chamber connected with said pipe, a blower in said pipe between the hot-air chamber and the pipe-terminal, and means for operating the blower.

2. In an apparatus for curing tobacco, the combination with a pipe

having an upwardly-directed bend terminating within the tobacco-chest, and provided at said upwardly-directed bend with a hood extended outwardly beyond the diameter of the pipe, and having an inverted-cone-shaped portion dependent into the opening in the pipe, and vertically adjustable, of a furnace having a hot-air chamber connected with said pipe, a blower in said pipe between the hot-air chamber and the pipe-terminal, and means for operating the blower.

3. In an apparatus for curing tobacco, the combination with a pipe having an upwardly-directed bend terminating within the tobacco-chest, provided with a series of externally-located staples and provided with a hood extended outwardly beyond the diameter of the pipe having an inverted-cone-shaped portion dependent into the opening in the pipe, and provided with a series of elongated eyes adapted for detachable engagement over said pipe-supported staples, of a furnace having a hot-air chamber connected to said pipe, a blower in said pipe between the hot-air chamber and pipe-terminal, and means for operating the blower.

4. In an apparatus for curing tobacco, the combination with a pipe terminating within the tobacco-chest, and having a portion thereof fitted through the side of the chest, of a truck having thereon a furnace provided with a hot-air chamber, a pipe leading from said chamber and having detachable connection with the portion of the pipe fitted through the side of the chest, a blower in said pipe between the hot-air chamber and its place of detachable connection as aforesaid, and means for operating the blower.

5. In an apparatus for curing tobacco, the combination with a pipe terminating within the tobacco-chest, and having a portion thereof fitted through the side of the chest, of a truck having thereon a furnace provided with a hot-air chamber, a pipe supported by the truck leading from said chamber having a detachable connection with the portion of the pipe fitted through the side of the chest, and having an aperture through its side, a blower having a pulley located in said pipe between the hot-air chamber and its place of detachable connection as aforesaid, a motor on said truck having a pulley, and a belt running around the motor-pulley and extending through the said pipe apertured to running engagement around said blower-pulley in the pipe, substantially as described.

6. In an apparatus for curing tobacco, the combination with a pipe terminating within the tobacco-chest, and having a portion thereof fitted detachably fitted through the side of the chest, of a truck having an apparatus for condensing the moisture in the air and provided with an air-entrance leading thereto, a furnace mounted on said truck having a hot-air chamber, an air-duct leading from the condensing apparatus to said chamber, another duct leading from said chamber and connected with the portion of the pipe terminating within the chest, a blower in the last-named duct, and means for operating the blower.

7. The combination with a tobacco-chest having a pipe terminating therewithin, and having a portion thereof fitted through the side of the chest, and a blower located in another opening in the side of the chest and pro-

vided with an externally-located operating-pulley, of a truck for employment outside the shed having mounted thereon a furnace having an air-chamber, a pipe supported by the truck connected with the air-chamber, and also having detachable connection with the portion of the pipe fitted through the side of the shed, a blower located within the pipe between the air-chamber and its point of detachable connection, having a pulley, a motor mounted on the truck having two pulleys, and belts in running engagement around the motor-pulleys and respectively around the blower-pulleys, substantially as described.

8. An apparatus for curing tobacco, the combination with the tobacco-shed having therein a pipe provided with an upwardly-opening bend, having an outwardly-widened head, which is provided with a conical portion depending within the opening in said pipe, and which head is vertically adjustable relatively to the pipe-bend, and said pipe having an end portion thereof fitted through an opening in the shed, and an outwardly-forcing blower located within another opening in the side of the shed, having an externally-located operating-pulley, of a truck outside the shed, having mounted thereon an apparatus for condensing the moisture in the air having an air-entrance opening therinto, a furnace having hot-air chamber, an air-conduit leading from the condensing apparatus to said chamber, a pipe leading from the hot-air chamber to detachable connection with the portion of the pipe opening through the side of the shed, and having apertures therein, a blower having a pulley located in the last-named pipe, a motor mounted on the truck and having pulleys and belts running therearound, one thereof extending through the apertures in the pipe for running engagement around the inclosed blower-pulley, and the other belt having running engagement around the pulley of the outwardly-forcing blower, substantially as and for the purposes set forth.

696,678. TAG. ROBERT G. HITT, Atlanta, Ga., assignor of one-fourth to Joseph H. Hitt, Augusta, Ga. Filed Apr. 23, 1901. Serial No. 53,084. (No model.)

Claim.—As an improved article of manufacture, a tag, for application to a cotton tie or band, formed of bendable sheet metal and comprising a body with a central opening in one side edge portion and a head diametrically opposed to said opening and projecting beyond the opposite side edge portion of the body, the opposite ends of the body being straight and the said opening providing projections which are bent over and lie parallel to the opposite end portions of the body to embrace the tie or band, the head being bent inwardly in a reverse direction and located between the bent projections in the opening forming the latter.

696,679. WRENCH. GEORGE R. HOWARD and JAMES LAURENCE, Jr., McKeesport, Pa. Filed Jan. 21, 1902. Serial No. 30,532. (No model.)

Claim.—1. A chain spanner attached to the movable jaw of a wrench and operating in a groove on the upper face of the handle thereof with overlapping flanges carried by the handle for securing said chain in position, substantially as described.

2. An adjustable chain spanner comprising a chain carrying a hook secured to the movable jaw of a wrench, the handle of said wrench on its rear end being arc-shaped with the upper face of the handle having a groove and overlapping flanges for securing said chain in position, substantially as described.

3. An adjustable chain spanner comprising a chain carrying a hook secured to the movable jaw of a wrench, the handle of said wrench on its rear end being arc-shaped with the upper face of the handle having a groove and overlapping flanges for securing said chain in position, and a fulcrum-arm secured in the handle, substantially as described.

4. An adjustable chain spanner comprising a chain carrying a hook secured to the movable jaw of a wrench, the handle of said wrench on its

rear end being arc-shaped with the upper face of the handle having a groove and overlapping flanges for securing said chain in position, and a spring-pressed fulcrum-arm secured in the handle, substantially as described.

5. An adjustable chain spanner comprising a chain carrying a hook secured to the movable jaw of a wrench, the handle of said wrench on its rear end being arc-shaped with the upper face of the handle having a groove and overlapping flanges for securing said chain in position, and a spring-pressed fulcrum-arm secured in the handle and having openings formed therein to receive the end of the said chain, substantially as described.

696,680. CHAIR ATTACHMENT. ALFRED E. HUNTING, Iron Mountain, Mich. Filed Feb. 23, 1901. Serial No. 49,304. (No model.)

Claim.—1. In an attachment of the class described, the combination with standards carrying chair-engaging means, of a seat having a pivotal connection with the standards and adjustable thereon, and a flexible connection between the upper portions of said standards and the outer portion of the seat, said connection being extensible to permit of the raising and lowering of the seat upon the standards.

2. In an attachment of the class described, the combination with standards carrying chair-engaging means and provided with a hook, of a seat having a pivotal connection with the lower portions of the standards and adjustable thereon, and a chain secured to the outer portion of the seat and having a detachable engagement with the hook of the standards, whereby the chain may be lengthened or shortened to permit of the raising and lowering of the seat upon the standard.

3. In an attachment of the class described, the combination with spaced upright supporting-standards, each having a head provided with depending hooks and intermediate eyes, of a seat pivoted between the lower portion of the standards and adjustable thereon, chains connected to the outer side portions of the seat and having a detachable engagement with the upper portions of the standards, side arms having depending hooks at their inner ends which engage the intermediate eyes of the standards, a tray secured to the outer portion of the arms, and links pivotally connected to the arms and having a detachable pivotal connection with the outer side portions of the seat.

696,681. DRAFT-EQUALIZER. JOSEPH D. DODGE, Birmingham, Tex. Filed Oct. 12, 1901. Serial No. 73,474. (No model.)

Claim.—1. A draft-equalizer comprising a main doubletree formed with a plurality of openings, supplemental doubletrees adjustably connected to the main tree, an over-bar also formed with a plurality of holes to adapt the draft connections between said bar and the main doubletree to be adjusted, a chain or cable attached to one end of the over-bar, a doubletree attached to the forward end of said chain, and a loop supported in front of the over-bar and carrying a roller.

2. In a draft-equalizer, the combination with a plurality of doubletrees, and an over-bar attached to the main doubletree, of a draft-chain attached to said over-bar, and a loop comprising parallel arms depending from said main doubletree and bent forward and connected by a cross-bar, and a roller loosely mounted on said cross-bar over which the chain passes.

696,682. FELLING AND BEMMING ATTACHMENT FOR SEWING-MACHINES. WILLIAM S. JENKINS, St. Louis, Mo., assignor of one-half to Christopher Allen Wiley, St. Louis, Mo. Filed Mar. 7, 1901. Serial No. 50,229. (Model)

Claim.—1. In an attachment of the character described, the combination with a presser-foot, having a prong projecting therefrom, of a spring B secured at one end to the prong, a frame projecting laterally toward the presser-foot supported by the outer end of the spring, a curling-finger projecting from said frame, and a curling-lip also projecting from said frame and bearing a fixed relation to the curling-finger, substantially as described.

2. In an attachment of the character described, the combination with a presser-foot having a prong projecting from the lower portion thereof, a spring secured to said prong, a frame supported by the outer end of the spring and occupying a plane substantially parallel with said prong, and felling or bemming device carried by said frame, substantially as described.

3. In an attachment of the character described, the combination with a footpiece, having a prong B projecting therefrom, of a spring secured at one end of said prong, a frame supported from the other end of the spring and carrying a curling-finger whose inner end is curved upwardly to form a pronounced curve, a curling-lip in juxtaposition to said curling-finger and projecting beneath the footpiece, and an adjustable frame carrying a spreading-finger and guide-shoe; substantially as described.

4. In an attachment of the character described, the combination with a presser-foot having a prong projecting from the lower portion thereof, a spring secured to said prong and bent upwardly and laterally at its outer end, a frame supported by said outer end of the spring and occupying a plane substantially parallel with said prong, and felling or bemming device carried by said frame, substantially as described.

5. In an attachment of the character described, the combination with a footpiece having a dotted needle-opening, of a prong B extending from said footpiece, a spring B carried by said prong and occupying a plane substantially parallel therewith its upper end projecting inwardly toward the foot, a curling-finger and curling-lip carried by the frame and approximately in alignment with the path of the needle, an adjustable frame D mounted upon the frame C and carrying a spreading-finger and guide-shoe, and means for locking said frame D in adjusted position; substantially as described.

6. In an attachment of the character described, the combination with a footpiece, of a frame, a spring supported from the foot having a portion bent inwardly toward the foot and carrying the frame, a curling-finger carried by said frame, a curling-lip cooperating with said finger and projecting beneath the footpiece, an adjustable frame mounted on the yielding frame, a spreading-finger on the horizontal plane of the curling-finger, and which is so shaped as to lie close to said curling-finger in one position of the parts, and a guide-shoe whose inner end projects beneath the footpiece; substantially as described.

7. In an attachment of the character described, the combination with a footpiece provided with a needle-opening and a prong B, said prong having a groove in its under surface extending across the same in substantial alignment with the needle-opening in advance of said opening, one wall of the groove being abrupt and the other wall thereof being gently curved, a frame supported by the prong B, and a curling-finger and curling-lip in the frame, substantially as described.

696,688. CHUTE. VAN WERT & JOHNSON, Washington, D. C. Filed Nov. 27, 1901. Serial No. 52,577. (No Model.)

Claim.—1. In apparatus of the class described, independent chutes having a common receiving-mouth, one of said chutes having an imperforate bottom, the bottom of the other being perforate, and separate means for controlling the passage-way through each chute whereby the material may be passed through either chute and immediately delivered screened or unscreened.

2. In apparatus of the class described, independent chutes located one below the other, said chutes having communication with each other contiguous to their upper ends, and means for closing said communication.

3. In apparatus of the class described, independent chutes having a common receiving-mouth inclined in the same direction, the bottom of one chute being imperforate and that of the other being perforate, and means for controlling the passage-ways through said chutes so that material may be passed through either and thereby delivered in screened or unscreened condition.

4. In apparatus of the class described, independent chutes located one below the other and inclined in the same direction, the bottom of the upper chute being imperforate, and that of the lower being perforate, said chutes having separate discharge ends located one below the other, and separate means for controlling the passage-way through each chute so that the material may be passed through either and thereby delivered in screened or unscreened condition.

5. In apparatus of the class described, independent chutes having communication at their upper ends, one of said chutes having an imperforate bottom, the other being provided with a perforate bottom, and means for controlling the passage-way through each chute so that material may be passed through either and thereby delivered in screened or unscreened condition.

6. In apparatus of the class described, independent chutes located one below the other and inclined in the same direction, said chutes having communication at their upper ends, the bottom of one chute being imperforate and the bottom of the other being perforate, and means for controlling the passage-way through each chute, so that the material may be passed through either and thereby delivered in screened or unscreened condition.

7. In apparatus of the class described, independent chutes located one below the other and inclined in the same direction, said chutes having communication with each other at their upper ends, means for closing the communication, and mechanism for controlling the passage-way through the upper chute.

8. In apparatus of the class described, independent chutes located one below the other and inclined in the same direction, said chutes having communication with each other at their upper ends, the bottom of the upper chute being solid and that of the lower being a screen, a slidably-mounted gate for closing the communication between the two chutes, and a movable gate for controlling the passage-way through the upper chute.

9. In apparatus of the class described, independent chutes located one below the other and inclined in the same direction, the upper chute having a solid bottom and the bottom of the lower chute being a screen, said chutes having communication with each other at their upper ends, a gate slidably mounted on the bottom of the upper chute and movable to close the communication between the two chutes, a hand-lever having a

connection with the gate, a gate slidably mounted on the lower end of the upper chute to control the passage-way therethrough, and a lever having a connection with said latter gate to move the same.

10. In apparatus of the class described, an inclined body having side walls, a bottom secured to said side walls above their lower edges forming thereabove a chute, and a screen detachably secured to the lower edge of said side walls.

11. In apparatus of the class described, an inclined body having side walls provided along their lower edges with guides, a bottom secured to said side walls above their lower edges and forming a chute, and a screen detachably mounted upon the guides.

12. In apparatus of the class described, an inclined body having side walls provided along their lower edges with interned supporting-flanges, a bottom secured to the side walls above their lower edges forming a chute, and a screen detachably mounted upon the supporting-flanges.

13. In apparatus of the class described, an inclined body having side walls, a bottom secured to said side walls above their lower edges and forming a chute, a screen detachably secured to the lower edge of the side walls, and a slack-coal receptacle mounted below the screen.

14. In apparatus of the class described, an inclined body having side walls, a bottom secured to the side walls above their lower edges forming a chute, a screen detachably secured to the lower edge of the side walls, a slack-coal receptacle having a pivotal connection with the lower end of the body, and a detachable hanger connecting the body and the other end of the receptacle.

15. In apparatus of the class described, independent chutes located one below the other and inclined in the same direction, the bottom of the upper chute being imperforate and that of the lower having a screen, the bottom of the upper chute having an opening at one end to establish communication with the lower chute.

696,684. SELF-LOCKING LATCH. JAMES H. KASER, Peoria, Ill.
Filed Dec. 16, 1901. Serial No. 86,131. (No model.)

Claim.—1. A latch comprising a casing, a sliding bolt mounted in the casing and provided with a notch or recess, and a vertically-movable catch or tumbler mounted within the casing and supported by the bolt and adapted to engage the recess automatically, said catch or tumbler being arranged to be operated by the finger and being wholly concealed within the casing, substantially as described.

2. A latch comprising a casing having vertical and horizontal ways, the vertical way extending to the bottom of the casing, a sliding bolt mounted in the casing, a vertically-movable catch or tumbler arranged in the vertical way and adapted to engage the bolt, and a movable plate mounted on the casing and covering the lower end of the vertical way, substantially as described.

3. A latch comprising independent casings 3 and 7 designed in its mounted on a door, and a door-frame and having vertical and horizontal ways, a horizontal bolt provided with notches and vertically-movable catches or tumblers mounted in the vertical ways and arranged to engage the said notches to lock the bolt in its extended and retracted positions and concealed wholly within the casings, substantially as described.

4. A latch comprising the casings 3 and 7 having vertical and horizontal ways, a horizontal bolt provided with notches, vertically-movable catches or tumblers mounted in the vertical ways and arranged to engage the notches for locking the bolt in its extended and retracted positions, and movable plates mounted on the casing and covering the lower ends of the vertical ways, substantially as described.

5. A latch comprising the casings 3 and 7 having vertical and horizontal ways, the casing 7 being also provided, adjacent to its vertical way with a recess 16, a horizontal bolt mounted in the horizontal way and provided with notches, and the vertically-movable catches or tumblers arranged in the vertical ways and recessed to receive the bolt, one of the catches or tumblers being provided with a projection operating in the recess 16, substantially as described.

6. A latch comprising a casing having vertical and horizontal ways

and provided at the horizontal way with a shoulder, a horizontal bolt arranged in the horizontal way and recessed to form opposite shoulders for engaging the said shoulder and the exterior of the casing, and a catch or tumbler mounted in the vertical way and arranged to engage the bolt, substantially as described.

7. A latch having its casing provided with a movable wall-section, and a finger-operated bolt-locking member arranged within the casing and exposed for actuation by the movement of said wall-section, substantially as described.

8. A latch comprising a casing having a movable wall-section, a finger-operated bolt, and a bolt-locking member arranged within the casing in position for engaging the bolt and adapted to be exposed for actuation by the movement of the said wall-section, substantially as described.

9. A latch comprising a casing having a movable wall-section, a sliding bolt mounted in the casing, and a finger-operated reciprocating bolt-engaging member located within the casing and exposed for actuation by the movement of the said wall-section, substantially as described.

10. A latch comprising a casing provided with a movable wall-section, a sliding bolt mounted in the casing and provided with a notch, and a vertically-movable finger-operated bolt-engaging member arranged within the casing in position for engaging the notch of the bolt, and exposed for actuation by the movement of said wall-section, substantially as described.

696,685. TRUNK. JAMES P. LEVERSON, Wrightsville, Pa.
Filed July 30, 1901. Serial No. 70,202. (No model.)

Claim.—1. A trunk comprising a plurality of sections superimposed one upon the other, said sections being hinged together at one side and provided with clasps at the opposite side; in combination with a ball-shaped locking-strap, the central portion of which is adapted to extend across the top of the trunk and the side arms of which are pivotally connected to the lower section, positioning-stays connected with said locking-strap, and a hump-bar connected with said locking-strap and carrying a pivotally-attached hump.

2. A trunk comprising a plurality of sections superimposed one upon the other, said sections being hinged together at one side and provided with clasps at the opposite side; in combination with a ball-shaped locking-strap embracing the several sections and pivotally connected to the opposite ends of the lower section, combined supports and stays connected to the locking-strap, a hump also connected to said locking-strap, and hand-grips mounted on said strap and arranged at opposite ends of the trunk.

3. A trunk comprising a plurality of sections superimposed one upon the other, said sections being hinged together at one side and provided with clasps at the opposite side; in combination with a pivotally-mounted locking-strap adapted to embrace the several sections of the trunk and also adapted to be swung to one side to form a support for the upper sections of the trunk when thrown open.

4. A trunk comprising a plurality of sections superimposed one upon the other, said sections being hinged together at one side and provided with clasps at the opposite side; in combination with an anchor-strap extending along the bottom of the lower section, a locking-ball pivotally connected at its ends thereto and adapted to extend over and embrace the remaining sections, and a hump pivoted to said ball.

5. The combination with a trunk having a cover pivoted thereto, of an anchor-strap having its ends upturned, a ball pivotally secured to said ends, combined supports and stays connected to said ball, and having their free ends bent to form hooks or clasps, a hump-bar pivoted to said ball, a hump pivoted to said bar, and hand-grips mounted on the arms of said ball.

696,686. MOLD FOR HOLDING MAPLE-SUGAR. JOSEPH M. LYON, Evanston, Ill.
Filed Sept. 20, 1901. Serial No. 76,906. (No model.)

Claim.—1. A mold of the class described, comprising a mold proper having its walls divided from top to bottom whereby said walls may be spread apart for releasing molded article, and a frame having relatively fixed and immovable sides adapted to engage the walls of the mold for holding them together, the mold being entirely removable from the frame, substantially as described.

2. A mold of the class described, comprising a mold proper having its walls divided from top to bottom whereby said walls may be spread apart for releasing the molded article, and a frame having relatively fixed and immovable sides, the mold being entirely removable from the frame, and the interior dimensions of the frame being the same as the exterior dimensions of the mold, whereby when the mold is forced into the frame, the latter contracts the former, substantially as described.

3. A mold of the class described having a mold proper, comprising a bottom and sides all made of a single piece of elastic sheet material, said sides being free to move independently of each other, and adapted to have their adjacent margins brought together, and means for holding said sides with their margins together as aforesaid, substantially as set forth.

4. A mold of the class described having a mold proper, comprising a bottom and sides all made of a single piece of elastic sheet material, said sides being normally divergent, free to move independently of each other and adapted to have their adjacent margins brought together, and means for holding said sides with their margins together as aforesaid, substantially as set forth.

5. A mold of the class described having a mold proper, comprising a bottom and sides all made of a single piece of elastic sheet material, said sides being free to move independently of each other, and adapted to have their adjacent margins brought together, and a frame surrounding the mold and engaging its sides whereby their adjacent margins are held together, substantially as set forth.

6. A mold of the class described having a mold proper, comprising a bottom and sides all made of a single piece of elastic sheet material, said sides being normally divergent, free to move independently of each other and adapted to have their adjacent margins brought together, and a frame surrounding the mold and engaging its sides whereby their adjacent margins are held together, substantially as set forth.

696,687. RULR. WILLIAM MEYER and OTTO G. MEYER, Shoberg, Wis. Filed Dec. 9, 1901. Serial No. 84,941. (No model.)

Claim.—1. In a device of the class described, the combination with a rule, of a gage-bar mounted upon one of the legs of the rule and having a head, an arm pivotally mounted on the other leg of the rule and adapted to extend from the latter, and a pivoted arm carried by the head of the gage-bar and adapted to be extended to cooperate with the said arm, substantially as described.

2. In a device of the class described, the combination with a rule, of a gage-bar mounted on one of the legs of the rule, and arms mounted one on the other leg of the rule and the other on the gage-bar and adapted to be folded, substantially as described.

3. In a device of the class described, the combination of a rule provided at one leg with a longitudinal way and having a groove at the outer and inner edge of the other leg, an arm pivoted in the groove and

arranged in fold within the same and to be arranged transversely of the rule, a gage-bar arranged in the said way and having a head provided with a groove, and an arm pivoted in the groove of the head and arranged to swing into the same, substantially as described.

4. In a device of the class described, the combination of a rule provided in one leg with a way, an approximately L-shaped support or casing mounted on the other leg and composed of sides spaced apart to form a groove, an arm pivoted in the support or casing and adapted to be extended therefrom, a gage-bar arranged in the said way and provided with a head having a groove, and an arm pivoted in the groove of the head and adapted to be swung outward therefrom to cooperate with the said arm, substantially as described.

696,688. RUBBER-TIRED WHEEL. RICHARD MUEHLHANS. Dunkirk, N. Y. Filed Aug. 20, 1901. Serial No. 73,572. (No model.)

Claim.—1. In a vehicle-wheel, a felly, a channelled rim superimposed thereon, a longitudinally-compressed elastic tire superimposed upon and fitting into said rim, a grooved retaining-band extending longitudinally through said tire, a bolt having a flat elongated head seating in said groove for connecting and securing the ends of the retaining-band together and forming a smooth outer joint; said bolt-head being held under compression between two opposed shoulders of the tire, substantially as set forth.

2. In a vehicle-wheel, a felly, a rim on said felly, a longitudinally-compressed tire on said rim having an interior longitudinal opening, a retaining-band in said opening having a channel and a bolt having an elongated head seated flush in the channel gripped longitudinally between shouldered parts of the tire and secured to the ends of the retaining-band, substantially as set forth.

3. In an elastic-tire wheel, a rim, a longitudinally-compressed tire on said rim, a channelled retaining-band extending longitudinally through the interior of the tire, a bolt having a flat head fitting flush into the channel in the retaining-band and connecting the ends of the band together whereby a smooth outer joint and band of uniform size throughout is obtained; the remaining space in the channel on the ends of the flat bolt-head being filled by a tongue projecting from the tire and having shouldered ends which press against the ends of the bolt-head, substantially as set forth.

4. In a vehicle-wheel, a rim, a tire longitudinally compressed on said rim and having an interior longitudinal opening, a retaining-band in said opening having a longitudinal channel in which a portion of said tire projects, said projecting portion being cut away at a certain point to leave a space and opposed shoulders, a bolt having an elongated head fitting in the space formed by cutting away a portion of the rubber and gripped between the opposed shoulders, and device, such as screws or rivets, securing the head of the two ends of the retaining-band.

5. In a vehicle-wheel, a felly, a channelled rim superimposed thereon, a longitudinally-compressed elastic tire superimposed upon and fitting into said rim and having a longitudinal groove, a grooved retaining-band of corresponding cross-section fitting in the groove in the tire and a bolt having an elongated head fitting flush in the groove in the retaining-band for connecting the ends of the retaining-band together; a portion of the tire within the groove of the retaining-band being cut away to leave a space for the bolt-head and the end walls of said space forming shoulders between which the said bolt-head is held under compression, substantially as set forth.

6. In a vehicle-wheel, a rim, a tire on said rim having a longitudinal angular opening wholly within its interior and a tongue extending into said opening nearly throughout its length, a retaining-band in the opening with its lower surface against and partially inclosing the tongue, a bolt having a head with projections extending into the retaining-band and into the under part of the tire for securing the ends of the band and ends of the tire together; a portion of the said tongue being removed for the reception of the head of the bolt, whereby the tongue in the tire the head of the bolt and the retaining-band is of uniform size throughout and a band of smooth outer surface is attained, substantially as set forth.

7. In a vehicle-wheel, a rim, a tire on said rim having a longitudinal angular opening wholly within its interior and a tongue extending into said opening nearly throughout its length, a retaining-band in the open-

ing partially inclosing the tongue, a belt having a head with projections extending into the retaining band and into the under part of the tire for securing the ends of the band and ends of the tire together; a portion of the said tongue being removed for the reception of the head of the belt.

8. In a vehicle-wheel, a rim, a tire on said rim having a longitudinal angular opening wholly within its interior and a tongue extending into said opening and cut away at one portion only in its circumference, a substantially U or C shaped retaining-band in the opening having its lower surface against and partially inclosing the tongue, a belt passing through the rim of the wheel and having a head extending into the retaining-band and fitting into the pocket formed by cutting away one portion of the tongue; the belt-head and tongue being of uniform width and thickness throughout, substantially as set forth.

9. In a vehicle-wheel, a felly, a channelled rim superimposed thereon, a longitudinally-compressed elastic tire superimposed upon and fitting into said rim and having a longitudinal opening and an interior longitudinal tongue, a grooved retaining-band extending through the opening in said tire, an elongated fastening device seating in said groove for connecting and securing the ends of the retaining-band together and forming a smooth outer joint; said fastening device being held under compression between two opposed shoulders of the tongue, and device, such as screws, passing through the retaining-band and fastening device and embedding in the tire, substantially as set forth.

10. In an elastic-tire wheel, a rim, a tire having an interior longitudinal opening and a tongue extending into the opening, a longitudinally-grooved retaining-band in the opening in the tire surrounding and partially inclosing the tongue, a belt having an elongated head in the groove of the retaining-band level with the outer edge thereof, and having projections through said band and in the under part of the tire for securing the ends of the retaining-band and the ends of the tire together, whereby a portion of the tongue of the tire being removed, the head of the belt fills its place and the retaining-band is left smooth on its outer surface and of uniform size throughout, as and for the purpose specified.

11. In an elastic-tire wheel, a rim, a longitudinally-compressed tire having an interior longitudinal opening and a tongue having a portion removed, a retaining-band in the opening in the tire having a longitudinal groove into which the tongue extends, a belt passing through the rim and having an elongated head in the groove of the retaining-band level with the outer edge thereof, and having projections through said band and in the under part of the tire for securing the ends of the retaining-band and the ends of the tire together, substantially as set forth.

12. In a vehicle-wheel, a felly, a rim on said felly, a longitudinally-compressed tire on said rim having an interior longitudinal opening and an interior longitudinal tongue, a retaining-band in said opening having a channel and a fastening device seating flush in the channel and gripped longitudinally between shouldered parts of the tongue; said fastening device being secured to the ends of the retaining-band, substantially as set forth.

13. In a vehicle-wheel, a felly, a channelled rim superimposed thereon, an elastic tire superimposed upon and fitting into said rim and having an interior longitudinal opening, a grooved retaining-band in said opening, a fastening device fitting flush within a portion of said groove for connecting and securing the ends of the retaining-band together and forming a smooth outer joint and a tongue of rubber projecting from the tire into the groove and filling said groove with the exception of that portion occupied by the fastening device, substantially as set forth.

14. In a vehicle-wheel, a solid rubber tire having an opening of an angular cross-section extending longitudinally through it; an angular hollow retaining-band fitting into said opening and having holes near its ends for the reception of screws or rivets, a T-belt having an elongated head fitting into the hollow in the retaining-band and having corresponding holes and screws or rivets fitting into said holes for securing the ends of the retaining-band together and having their lower ends projecting into the tire, as and for the purpose specified.

696,689. DRESS-SHIELD HOLDER. JOHN F. MURPHY, Adrian, Mich., assignor to George R. M. Senger and Herbert R. Clark, Adrian, Mich. Filed Feb. 14, 1901. Serial No. 47,366. (No model.)

Claim.—1. A dress-shield spreader and holder, comprising a substantially annular spreader-body corresponding in curvature to the concave edge of a dress-shield and adapted to be arranged wholly within the light or fold thereof, an intermediate portion of the spreader-body being provided with means projected at its concave side for engagement with the arm-eyes of a dress-waist to anchor the intermediate portion of the spreader-body and prevent upward bulging thereof, and means for fastening the spreader-body to a shield.

2. A dress-shield having an arcuate spreader fitted snugly within and against the back portion of the light thereof and connected to said back portion only, the remaining portion of the shield being entirely free

from the spreader, the latter comprising a plurality of members disposed in longitudinal succession with their adjacent ends overlapped and pivotally connected, and mutually-cooperating garment-engaging clamp members carried by the adjacent members of the spreader.

3. A dress-shield having an arcuate spreader fitted snugly within and against the back portion of the light thereof and connected to said back portion only, the remaining portions of the shield being entirely free from the spreader, and the latter comprising flexibly-jointed members disposed in longitudinal succession, and mutually-cooperating garment-engaging clamp members carried by the adjacent spreader members.

4. A dress-shield, having a spreader fitted snugly within and against the back portion of the light thereof and connected to said back portion only, the remaining portions of the shield being free from the spreader, the latter comprising a series of members made of flat material pivotally connected at their meeting ends, and provided at their terminals with co-operating arm-eyes-engaging clamp members.

5. A dress-shield having a spreader fitted snugly within and against the back portion of the light thereof, and connected to said back portion only, the remaining portions of the shield being free from the spreader, the latter comprising a series of flexible pivotally-connected members disposed in a curved series, and an arm-eyes-engaging clamp member carried by each member of the spreader.

6. A dress-shield, having a spreader carried snugly within and against the back portion of the light thereof, and connected to said back portion only, the remaining portions of the shield being entirely free from the spreader, the latter being formed by three arcuate members disposed in longitudinal succession, the opposite ends of the intermediate member being overlapped by and pivotally connected to the inner ends of the respective terminal members, and mutually-cooperating garment-engaging clamping members carried by the ends of the intermediate spreader member and the inner ends of the respective terminal members.

7. A spreader and holder for dress-shields, consisting of an arcuate body formed by a plurality of arcuate members disposed in longitudinal succession, the adjacent ends of opposite members being pivotally connected, each member having means for connection with the light of a dress-shield, and mutually-cooperating arm-eyes-engaging members carried by adjacent members of the arcuate spreader.

8. A spreader and holder for dress-shields, having pivotally-connected arcuate members disposed in longitudinal succession, one of which is provided with a laterally-extending clamp member which is extended from the concave side of the spreader member and projected beyond the convex side thereof, and the other spreader member having a clamp member which is projected transversely from the convex edge of the spreader and constructed to lie across and cooperate with the other clamp member for engagement with an arm-eyes when the spreader members are brought into longitudinal alignment.

696,690. EDUCATIONAL DEVICE. JOHN E. MURRAY, Washington, Pa. Filed Aug. 9, 1901. Serial No. 71,452. (No model.)

Claim.—An educational device comprising in its entirety, a flat circular disk having an hour-hand and a minute-hand centrally and movably mounted thereon, an inner and outer margin on said disk divided by circular lines, Roman characters arranged on said inner margin the inner margin having arranged beneath each Roman character its Arabic equivalent for the hour-hand, and the outer margin having arranged above each Roman character its equivalent in Arabic numerals for the minute-hand, and the words "Full hour" and "Half hour" arranged on the outer margin above the Roman characters "XII" and below the Roman characters "VI," the said hour-hand and minute-hand adapted to be revolved by the hand of the instructor whereby different hours and minutes may be readily indicated for the instruction of the pupil, substantially as described.

696,691. VALVE FOR ENGINE. JOHN G. MCCORMACK, Cleveland, Ohio. Filed June 22, 1901. Serial No. 65,664. (No model.)

Claim.—1. In an engine, the combination of a cylinder and heads thereon, each head having a duct and a valve-chamber between said duct and the cylinder and aligned ports between the valve-chamber and said duct and between the valve-chamber and the cylinder, and a valve in said valve-chamber, having a duct to connect said ports and form free passages or ducts between the first-mentioned duct and the cylinder.

2. In an engine, the combination of a cylinder, heads on the ends thereof, each head having a valve-chamber, a duct behind the valve-chamber, and ports between the valve-chamber and duct and the valve-chamber and cylinder, and a rotary valve in said valve-chamber having ducts to align with all of said ports.

3. In an engine, the combination with a cylinder, of heads secured thereto, each head having two ducts therein, one for live steam and the other for exhaust, and having two valve-chambers located between the respective ducts and the inner face of the cylinder-head, aligned ports connecting the valve-chambers with the cylinder and with said ducts, valves in said valve-chambers, each of said valves having ducts extending transversely through the same and adapted to connect the aligned ports.

4. In an engine, the combination of a cylinder having a live-steam duct and an exhaust-steam duct in its wall, heads on the ends of said cylinder, each head having two valve-chambers communicating with the ends of the cylinder, and each head having two ducts extending behind the respective valve-chambers and communicating with the latter through ports in line with the axis of the cylinder, the ducts in the heads communicating with the live-steam and exhaust ducts, and a valve in each valve-chamber, each of said valves having ducts extending transversely through the same, substantially as and for the purpose set forth.

5. A valve for engines having a general cylindrical shape and parallel ports extending throughout the greater portion of the length of the valve, and a brace-rod extending transversely through all the ports of the valve and bracing all the walls of said ports.

696,692. WATER-METER. LEWIS E. HARR, South Norwalk, Conn., and FREDERICK S. KING, Brooklyn, N. Y., assignors to the National Meter Company, New York, N. Y., a Corporation of New York. Filed July 7, 1901. Serial No. 642,782. (No model.)

Claim.—In a water-meter the combination of a meter-chamber, a substantially air-tight chamber containing the registering mechanism, an open intermediate space between said chambers, and a spindle communicating the motion of the piston to the dial mechanism passing through said intermediate space with a yielding joint-forming substance where the spindle enters said dial-chamber.

696,692.

696,698. DEVICE FOR HOLDING AND RELEASING FIRE DOORS. PHILIP CLARK, Chicago, Ill., assignor of two-thirds to Albert L. Deane, Chicago, Ill., and James W. Donnell, Evanston, Ill. Filed June 14, 1901. Serial No. 64,584. (No model.)

Claim.—1. In a device of the class described the combination of a latch-lever having a pair of jaws adapted to receive between them a part carried by the door, a trip-lever adapted to engage the latch-lever, thermoelectric devices for releasing the trip-lever when subjected to a predetermined temperature and a trigger adapted to engage the trip-lever for tripping it manually substantially as described.

2. In a device of the class described the combination of a latch-lever having a pair of jaws adapted to receive between them a part carried by the door, one of said jaws being arranged in and the other out of the path of said part when the door is closed, a spring arranged in the path of the latch-lever for holding it in the position last described so that as the door opens said part carried by it will engage one jaw of the latch-lever and thereby shift it bringing the other jaw into the path of said part, a trip-lever adapted to automatically engage the latch-lever, a thermoelectric appliance for automatically tripping the trip-lever when subjected to a predetermined temperature substantially as described.

696,694. MOTOR-VEHICLE. EDWARD J. FRIEDMAN, London, England, assignor of one-half to J. W. Plank and George Edward Mills, Carlisle, Pa. Filed June 28, 1901. Serial No. 65,722. (No model.)

Claim.—In a motor-driven vehicle, the combination of driving-wheels, each mounted in a fork or standard, comprising or embodying the independent motor or driver of said wheel; a generator or distributor of motive power common to each of said motors; means for independently conveying or transmitting power to each individual motor, and an independent reversing device for each motor, whereby the vehicle may be steered by varying the peripheral speeds of the driving-wheels or changing the direction of certain of said wheels with respect to the direction of other wheels, substantially as set forth.

696,694.

696,695. HORSESHOE. HARRY C. FORTER, Pittsburg, Pa. Filed Dec. 27, 1901. Serial No. 57,407. (No model.)

Claim.—1. In a horseshoe of the character described, the combination of a plate, a horseshoe having out-away portions at its ends and having wedge-shaped openings formed therein, said horseshoe having a recess and a wedge-shaped opening formed in the toe thereof, removable calks and a toe-plate carrying a square shank and wedge-shaped heads registering with said wedge-shaped openings in the horseshoe, and means whereby said calks and toe-plate are retained in position, substantially as set forth.

2. In a horseshoe of the character described, the combination of a plate, a horseshoe having out-away portions at its ends and having wedge-shaped openings formed therein, said horseshoe having a recess and a wedge-shaped opening formed in the toe thereof, removable calks and a toe-plate carrying a square shank and wedge-shaped heads registering with said wedge-shaped openings in the horseshoe, and set-screws secured in the ends and toe of said horseshoe to prevent the displacement of said calks and toe-plate, substantially as described.

696,696. DIAPHRAGM-PUMP. WILLIAM F. RUSSELL, Newburyport, Mass. Filed Sept. 20, 1901. Serial No. 75,812. (No model.)

Claim.—In a diaphragm-pump, the combination of the diaphragm and plunger, said structure formed with an outlet from the pump-chamber, the plunger including a plate attached to the diaphragm and provided with a plurality of uprights on opposite sides of the outlet, a detachable cross head or beam connected to the upper ends of said uprights and integrally formed with a plurality of downwardly-projecting lugs conforming to the uprights and constituting elongated bearings between said uprights and the cross-head, said lugs being also arranged to act as upper stops for the outlet-valve, and an outlet-valve supported by the diaphragm and plunger structure and controlling said outlet, the said valve being adapted to encounter said lugs in its upward movement.

696,697. HARROW-JACK. ELMER W. THOMSON, Elgin, Ore. Filed Aug. 31, 1901. Serial No. 72,905. (No model.)

Claim.—1. The combination with a harrow, of a jack having a central longitudinal slot wherein it is loosely connected therewith.

2. The combination with a harrow, of a reversible jack pivotally mounted in the rear of the harrow and connected with the frame thereof.

3. The combination with a harrow having rearwardly-projecting bars, of a jack pivotally mounted between said bars, and means for holding and releasing the jack.

4. The combination with a harrow, of a jack pivotally mounted in rear of the harrow and connected therewith, and a trip-lever arranged to have a portion thereof moved into and out of the path of the jack.

5. The combination with a harrow, of rearwardly-converging bars projecting therefrom, a centrally-slotted jack pivotally mounted between said bars, a trip-lever for holding and releasing said jack, a spring for retracting said trip-lever, and means for operating the trip-lever.

6. The combination with a harrow, of rearwardly-converging bars extending backward therefrom, a bolt or axle connecting the rear ends of said bars, a jack having a centrally-arranged longitudinal slot which receives said bolt or axle and adapts the jack to be slid longitudinally, and a tripping device for holding and releasing the jack.

696,698. BUTTONHOLE-MACHINE. ROBERT W. THOMSON, Lynn, Mass., assignor to Howe Buttonhole Machine Company, Boston, Mass., a Corporation of Maine. Filed Jan. 20, 1902. Serial No. 412,670. (No model.)

Claim.—1. In a machine for stitching buttonholes, stitch-forming mechanism comprising a reciprocating eye-pointed needle, and complementary means cooperating therewith to form a series of overedge-stitches, a work-clamp to hold the material having the slit to be overstitched entirely about its edge, means to change automatically the relative positions of said work-clamp and stitch-forming mechanism, whereby over-edge-stitches are made at both ends of the buttonhole-slit and at both

sides thereof, the overedge-stitching which completes the stitching of the buttonhole overlapping overedge-stitching made when starting the buttonhole.

2. In a machine for stitching buttonholes, stitch-forming mechanism comprising a reciprocating eye-pointed needle, and complementary means cooperating therewith to form a series of overedge-stitches, a work-clamp to hold the material having the slit to be overstitched entirely about its edge, means to change automatically the relative positions of said work-clamp and stitch-forming mechanism, whereby overedge-stitches are made at both ends of the buttonhole slit and at both the sides thereof, the overedge-stitching which completes the stitching of the buttonhole, overlapping overedge-stitches made when starting the buttonhole and means to stop automatically the stitch-forming mechanism when the buttonhole has been completed by the overlapping of the overedge-stitching.

3. In a machine for stitching buttonholes, stitch-forming mechanism comprising a reciprocating eye-pointed needle, and complementary means cooperating therewith to form a series of overedge-stitches, a work-clamp to hold the material having the slit to be overstitched entirely about its edge, means to change automatically the relative positions of said work-clamp and stitch-forming mechanism, whereby overedge-stitches are made at both ends of the buttonhole slit and in both sides thereof, the overedge-stitching which completes the buttonhole overlapping overedge-stitching made when starting the buttonhole, means to stop automatically the stitch-forming mechanism after the overedge-stitching has been overlapped, and means to thereafter continue to further change the relative positions of the work-clamp and stitch-forming mechanism at a faster speed than when overedge-stitching is being done and while the needle of the stitch-forming mechanism is out of the work, to locate the clamp in the position it must occupy for the removal of the material therefrom containing the buttonhole.

4. In a machine for stitching buttonholes, stitch-forming mechanism consisting of a reciprocating eye-pointed needle, and complementary means cooperating therewith to form a series of overedge-stitches, a work-clamp to hold the material having the slit to be overstitched entirely about its edge, means to change the relative positions of said work-clamp and stitch-forming mechanism whereby both ends of the buttonhole-slit, one end having an enlarged eye, and the sides of the slit may be overstitched, the overedge-stitching which completes the buttonhole overlapping the stitching made when starting the buttonhole, and means to cut the material held in the clamp preparatory to stitching the same.

5. In a sewing-machine for stitching buttonholes, stitch-forming mechanism comprising a reciprocating eye-pointed needle, and complementary means cooperating therewith to form a series of overedge-stitches, a work-clamp to hold the material having the slit to be overstitched, means to partially rotate the work-clamp while overstitching each end of a buttonhole, said partial rotations being in the aggregate more than a full rotation during the stitching of each buttonhole, whereby the overedge-stitching which completes the buttonhole is made to overlap overedge-stitching made to start the buttonhole.

6. A sewing-machine containing the following instrumentalities, viz: stitch-forming mechanism comprising an eye-pointed needle and an under-thread-carrying looper, means to maintain the same to form overedge-stitches, a work-clamp to hold the material, a carrier to sustain said clamp, means to move said clamp longitudinally in said carrier while the side edges of the buttonhole are being stitched, and means to partially rotate said carrier and work-clamp while overstitching each end of a buttonhole, said partial rotations being for more than a full rotation during the stitching of each buttonhole, whereby the overedge-stitching which completes the buttonhole is made to overlap overedge-stitching made to start the buttonhole.

7. In a buttonhole-stitching machine, a work-clamp, stitch-forming mechanism, and means to change the relative positions of said clamp and stitch-forming mechanism to enable overedge-stitches to be made entirely about the edge of the buttonhole, the last of the overedge-stitching overlapping the overedge-stitching made at the point where the stitching was commenced.

8. In a machine for stitching buttonholes, stitch-forming mechanism consisting of a needle to penetrate the material, and complementary means cooperating therewith to form a series of overedge-stitches, a work-clamp, means to slide the work-clamp while the stitch-forming mechanism makes a series of overedge-stitches along the sides of the buttonhole, means to change the relative positions of the work-clamp and stitch-forming mechanism relatively while the stitch-forming mechanism is operating to make a series of overedge-stitches radiating about both ends of the buttonhole, the stitching that completes the overedge-stitching of the buttonhole overlapping overedge-stitching made when the stitching of the buttonhole was commenced.

9. In a machine for sewing buttonholes, overedge-stitch-forming mechanism, a carrier, a plate slidably mounted therein, a work-clamp pivoted on said plate, means to engage said carrier a plurality of times

to effect a partial rotary movement of said carrier and clamp during the overstitching of both ends of a buttonhole, means to slide said clamp in said carrier between partial rotations of the carrier, and means to swing said clamp on said plate during the time that the large eye of the buttonhole is being overstitched.

10. In a machine for stitching buttonholes, stitch-forming mechanism comprising an eye-pointed needle to penetrate the material, and complementary means cooperating therewith to form a series of overedge-stitches, a work-clamp to contain the material having the buttonhole the edge of which is to be overstitched, means to change the relative position of said work-clamp and stitch-forming mechanism while a series of overedge-stitches is being made along both sides of and about both ends of the buttonhole-slit, means to stop the action of the stitch-forming mechanism when the buttonhole has been overstitched, and means to thereafter move the work-clamp at a faster speed to place said clamp in the position from which it was started when the overstitching of the edge of the buttonhole was begun.

11. In a machine for stitching material, stitch-forming mechanism comprising an eye-pointed needle to penetrate the material, and complementary means cooperating therewith to form a series of overedge-stitches, means to clamp the material having the edge to be overstitched, and means to change the relative position of the said work-clamp and stitch-forming mechanism for a cycle of movements, and means to stop the action of the stitch-forming mechanism at the completion of the cycle of movement, the stitch-forming mechanism during each cycle of movement overstitching the beginning of the line of stitching before said stopping mechanism acts.

12. In a machine for stitching buttonholes, stitch-forming mechanism comprising an eye-pointed needle to penetrate the material back of the edge of the slit therein, and complementary means working through said slit and cooperating with the eye-pointed needle to form a series of overedge-stitches, a work-clamp, means to change the relative position of said work-clamp and stitch-forming mechanism at one speed while overstitching the side edges of a buttonhole-slit, means to change the relative position of said parts at a faster speed while stitching both ends of the buttonhole-slit, means to stop the stitching action of the stitch-forming mechanism, and means to thereafter continue said relative change of position of said work-clamp and stitch-forming mechanism at a yet faster speed while the stitching action is suspended to thereby put the work-clamp in its starting position for change of material therein.

13. In a machine for stitching buttonholes, overedge-stitch-forming mechanism, a work-clamp, a plate upon which said work-clamp is pivotally mounted, means to move said work-clamp longitudinally while stitching the sides of a buttonhole, means to rotate said clamp partially while stitching the large eye of the buttonhole, and means to swing said clamp on said plate while stitching about the large eye of the buttonhole, and while the stitching at the sides of the buttonhole is approaching and leaving said large eye.

14. In a sewing-machine, for sewing buttonholes, overedge-stitch-forming mechanism a carrier, a plate, a work-clamp mounted on said plate and free to be slid longitudinally in said carrier, a pusher, means to rotate said carrier and slide said plate therein at intervals, and a ring having an eccentric inner edge to act upon said pusher to swing the work-clamp on said plate while stitching about the eye of a buttonhole.

15. In a buttonhole-sewing machine, a work-clamp having at one edge straight and concaved portions, a plate having a pivot to sustain the work-clamp, a spring connecting said plate and clamp, and a carrier adapted to receive and guide the plate upon which the work-clamp is mounted, said carrier being provided with a stud against which the straight and concaved portions of said clamp act while stitching the sides of a buttonhole near the enlarged eye at one end thereof.

16. In a machine for sewing buttonholes, a rotatable carrier dotted centrally and provided at one side of said slot with a stud, a plate entering the slot of the carrier, and having pivoted upon it a work-clamp provided with a cam-shaped edge, means to move said plate and clamp in said carrier, a spring to keep the cam shaped edge of the work-clamp in contact with said stud, the stud and spring controlling the extent of lateral swinging movement of the clamp on the plate during the stitching of the sides of a buttonhole near the enlarged eye and thereof.

17. In a buttonhole-stitching machine, stitch-forming mechanism for making an overedge-stitch, a work-clamp to hold the slitted material the edge of which is to be overstitched, means to partially rotate said clamp when the buttonhole-stitching is commenced, means to thereafter restrain the rotation of said clamp and slide the same in the direction of the length of the buttonhole when one side of the buttonhole is being stitched, means to again partially rotate the clamp while one end of the buttonhole is being stitched, and again move the clamp in the direction of the length of the buttonhole while the opposite side edge of the hole is being stitched, and again impart circular movement to the work-clamp in the same direction while the end of the buttonhole at which the stitching was started

is completely stitched around to a point beyond the point where the stitching was started.

18. In a buttonhole-stitching machine, stitch-forming mechanism to form a series of overedge-stitches, a work-clamp to hold the material having the buttonhole to be overstitched, a clamp-actuating ring provided with a series of teeth, a shaft having a toothed gear to engage the teeth of said ring to move the same during the overstitching of the edge of the buttonhole, and means to uncouple said gear from the teeth of said ring when the overstitching of the buttonhole has been carried completely about the edge thereof.

19. In a buttonhole-stitching machine, stitch-forming mechanism to form a series of overedge-stitches, a work-clamp to hold the material having the buttonhole to be overstitched, a clamp-actuating ring provided with a series of teeth, a shaft having a toothed gear to engage the teeth of said ring to move the same during the overstitching of the edge of the buttonhole, means to uncouple said gear from the teeth of said ring when the overstitching of the buttonhole has been carried completely about the edge thereof, and means to engage said ring and move the same that it may carry the clamp holding the stitched buttonhole into position to receive the material.

20. In a buttonhole-stitching machine, stitch-forming mechanism, a work-clamp occupying normally a starting position, means to turn said clamp in one direction while overstitching a buttonhole, a carrier for said clamp, a toothed ring, a shaft having a pinion adapted to engage said toothed ring and having a worm-gear, combined with a shaft having a worm, devices to cause said worm to engage said worm-gear and rotate the shaft upon which it is mounted to turn backwardly said toothed ring and return the work-clamp into its starting position, and means to thereafter disengage said worm from said gear and leave said shaft at rest with the clamp in its starting position.

21. In a buttonhole-stitching machine, a work-clamp, a toothed ring to move said clamp while stitching a buttonhole, said ring having a series of inner teeth, a shaft having a pinion to engage said teeth, and a worm-toothed gear, said pinion and shaft occupying their inoperative position while stitching a buttonhole, a sleeve having a worm, and means to automatically move said sleeve that its worm may engage the said worm-gear and rotate said shaft and pinion that it may rotate the said toothed ring backwardly and cause it to return the work-clamp into its starting position.

22. In a machine for stitching buttonholes, stitch-forming mechanism, a work-clamp, a carrier for said clamp, a ring having two series of teeth, a cam to move said clamp longitudinally in said carrier, means engaging one series of said teeth to move the said ring in one direction while stitching a buttonhole, means to engage automatically the other of said series of teeth after the completion of a buttonhole to further turn said ring and clamp automatically into its starting position, and means to stop the shaft and ring after the clamp has been brought to its starting position.

23. In a buttonhole-stitching machine, a carrier, a clamp therein, a toothed ring having gear-teeth, a series of bevel-teeth, a beveled toothed gear to engage said bevel-teeth and rotate said ring in one direction during the stitching of a buttonhole, a shaft having a pinion engaging the gear-teeth of said ring and moved by the ring during the stitching of a buttonhole, means to disengage the teeth of the bevel-gear from the bevel-teeth of said ring after stitching a buttonhole, and devices to thereafter automatically engage and rotate the shaft carrying the said pinion in a direction to reverse the movement of said toothed ring, together with said carrier and work-clamp to bring the clamp into its normal starting position after the completion of a buttonhole.

24. In a sewing-machine for stitching buttonholes, the following instrumentalities, viz: stitch-forming mechanism, a rotating work-clamp actuating-ring provided with a series of teeth, a work-clamp, and carrier, a rotating shaft and gear to engage the teeth of said ring and rotate it forwardly while a buttonhole is being stitched, a series of internal teeth also made in said ring, a rotating shaft provided with a pinion to engage said internal teeth to put the clamp into its starting position.

25. In a sewing-machine for stitching buttonholes, stitch-forming mechanism, a work-clamp, a carrier in which it is mounted to slide, a toothed ring, a shaft to actuate said ring to move said carrier and clamp during the stitching of a buttonhole, means to stop the stitch-forming mechanism when the entire edge of the buttonhole has been overstitched, a clutch on said shaft containing as part thereof a continuously-running pulley, a second shaft driven from said continuously-running pulley when the shaft operating said work-clamp and its carrier is at rest, and actuating means between said second shaft and said toothed ring to further turn said ring to place the work-clamp in its starting position while the stitch-forming mechanism is at rest.

26. In a machine for stitching buttonholes, stitch-forming mechanism to form overedge-stitches, a work-clamp to hold the material, means to rotate said clamp partially at intervals and to move said clamp longitudinally between said partial rotations, and means to stop the action of

the stitch-forming mechanism after the overedge-stitching at both ends of the buttonhole across the center line of the slit.

27. In a buttonhole-stitching machine, stitch-forming mechanism, a rotatable carrier having opposite notches or projections at its edge, and containing a sliding work-clamp, a table-plate to contain said carrier, holding means to engage one after the other the notches or projections of the carrier to restrain its rotation while the straight sides of the buttonhole are being stitched; a toothed ring having a projection; a shaft having an attached gear to rotate said ring; means to move said shaft at two different rates of speed while stitching a buttonhole, the said shaft having its slower speed while the sides of the buttonhole are being stitched the projection of said ring meeting said holding means and putting out of operation the slower shaft-moving means after stitching each side of a buttonhole letting the faster-moving means come into operation while the rounded ends of the buttonhole are being attached.

28. In a machine for stitching buttonholes, a work-clamp, buttonhole-cutting mechanism, and stitch-forming mechanism; combined with means controlled by said cutting mechanism to automatically start the stitch-forming mechanism into operation after the cutter has been actuated to do its work.

29. In a machine for sewing buttonholes, a work-clamp, buttonhole-cutting mechanism to cut a buttonhole and remove a portion of the material to leave an enlarged eye at one end of the hole, stitch-forming mechanism, and means to change the relative positions of said clamp and stitch-forming mechanism to enable overedge-stitches to be made entirely about the edge of the buttonhole, the last of the overedge-stitching made at the point where the stitching was commenced.

30. In a machine for stitching buttonholes, a work-clamp, buttonhole-cutting mechanism to cut a buttonhole in the material held in the clamp, stitch-forming mechanism, means to change the relative positions of said clamp and stitch-forming mechanism to enable overedge-stitches to be made entirely about the edge of the buttonhole, the last of the overedge-stitching overlapping the overedge-stitching made at the point where the stitching was commenced, and means to stop the stitch-forming mechanism when the overedge-stitching has been overlapped.

31. In a machine for stitching buttonholes, a work-clamp, buttonhole-cutting mechanism to cut a buttonhole in the material held in the clamp, stitch-forming mechanism, means to change the relative positions of said clamp and stitch-forming mechanism to enable radiating overedge-stitches to be made entirely about the edge of the buttonhole, means to stop the stitch-forming mechanism when the entire edge of the buttonhole including its sides and both ends have been overstitched by radiating stitches, and means to thereafter further move relatively the clamp and stitch-forming mechanism while the latter is inoperative to place the clamp in starting position ready for the stitching of another buttonhole.

32. In a machine for stitching buttonholes, a work-clamp, buttonhole-cutting mechanism to cut a buttonhole, stitch-forming mechanism to form a series of overedge-stitches, means controlled by the cutting mechanism to start into operation the stitch-forming mechanism, means to change the relative positions of said clamp and stitch-forming mechanism, whereby the stitching along the sides of the buttonhole is made at one speed, the overedge-stitching about the ends of the buttonhole being made at an increased speed, means to stop the stitch-forming mechanism at the completion of the overedge-stitching, and means to thereafter further change the relative positions of the work-clamp and stitch-forming mechanism while the stitch-forming mechanism remains inactive to place the work-clamp holding the stitched buttonhole in the position at which the material was applied to the clamp to be stitched.

33. In a machine for stitching buttonholes, a work-clamp, buttonhole-cutting mechanism to cut a buttonhole, stitch-forming mechanism to form a series of overedge-stitches, means controlled by the cutting mechanism to start into operation the stitch-forming mechanism, means to change the relative positions of said clamp and stitch-forming mechanism, whereby the stitching along the sides of the buttonhole is made at one speed, the overedge-stitching about the ends of the buttonhole being made at an increased speed, means to stop the stitch-forming mechanism at the completion of the overedge-stitching, means to thereafter further change the relative positions of the work-clamp and stitch-forming mechanism while the stitch-forming mechanism remains inactive to place the work-clamp holding the stitched buttonhole in the position in which it received the material to be stitched, and means to lock the clamp in its position to receive the material.

34. In a buttonhole-stitching machine, stitch-forming mechanism adapted to make overedge-stitches, a work-clamp, means to change the relative positions of said stitch-forming mechanism and work-clamp in the overstitching of the edge of a buttonhole, clutch mechanism, buttonhole-cutting mechanism, and devices controlled by the return into its inoperative position of the buttonhole-cutting mechanism to operate the clutch mechanism and start the stitch-forming mechanism into operation.

35. In a machine for stitching buttonholes, stitch-forming mechanism adapted to make overedge-stitches, and having as a part thereof a throat-plate adapted to be raised and lowered with relation to the material being stitched, a work-clamp, buttonhole-cutting mechanism the lower member of which occupies normally a position at one side the throat-plate of the stitch-forming mechanism and with its face below the face of said throat-plate, said work-clamp being adapted to be put into position between the members of said cutting mechanism and out of stitching position, means to return the clamp into stitching position after cutting the material therein, and means to start the stitch-forming mechanism automatically after the cutting of the buttonhole, and means to change the relative positions of said work-clamp and stitch-forming mechanism to make a series of overedge-stitches.

36. In a buttonhole-sewing machine, stitch-forming mechanism for producing overedge-stitches, a work-clamp, means to lock said clamp in the position in which the work is to be changed therein, a spring acting normally to keep said work-clamp in its operative position for stitching a buttonhole, and cutting mechanism, said clamp being free to be slid longitudinally against said spring to put the clamp in position to have the material held by it cut by the buttonhole-cutting mechanism, and device actuated by the cutting mechanism when coming into its inoperative position to start into operative position the stitch-forming mechanism.

37. In a buttonhole-sewing machine, a table-plate, a carrier rotatably mounted in said table-plate and provided at its edge with a notch, a work-clamp slidably mounted in said carrier, buttonhole-cutting mechanism, a dog to enter the notch of the carrier to restrain its rotation while the work-clamp is moved longitudinally in said carrier to place the material held therein between the members of the buttonhole-cutting mechanism that the latter may be operated to cut a slit in the material.

38. In a sewing-machine for stitching buttonholes, a carrier, a clamp mounted therein, a work-clamp-actuating toothed ring, a bevel-gear engaging the said toothed ring, a shaft carrying said bevel-gear, two sets of shaft-actuating devices for rotating the shaft carrying said bevel-gear, the first set being adapted to move said shaft intermittently for a greater distance at each throw than the second set, a locking device for the first set of shaft-actuating devices, and controlling device controlled by said ring to cause said locking device to operate while the second set of said devices operates to move the ring and clamp in stitching the straight sides of the buttonhole, said ring when the ends of the buttonhole are to be stitched permitting said devices to be moved to unlock said first set of shaft-actuating devices to turn said shaft and the said toothed ring at a faster speed during the operation of stitching about the ends of a buttonhole.

39. In a sewing-machine, the following instrumentalities, viz: a work-clamp to hold the material, a rotatable carrier in which the said work-clamp may slide, stitch-forming mechanism, a shaft for effecting the rotation of said carrier, two sets of actuating devices for operating said shaft, one set moving said shaft for a greater distance at each stitch than the other set, and means to effect the locking out of operation, while stitching, the straight sides of the buttonhole of the said actuating devices for moving said shaft its greatest distance, said actuating device, however, moving said shaft while the overedge-stitching is carried about the ends of the buttonhole, whereby the stitching of the sides of the buttonhole may be effected by a short stitch and about the eye by a longer stitch.

40. In a buttonhole-sewing machine, stitch-forming mechanism, a work-clamp adapted to hold stretched the material in which the buttonhole is being stitched throughout the stitching operation, means to move said work-clamp while holding the material to feed the same, combined with a throat-plate normally supporting the material within the open central portion of said closed clamp during the stitching operation, and means to lower said throat-plate from contact with the material during the feeding operation, thereby relieving the material from the friction of the throat-plate.

41. In a buttonhole-sewing machine, the combination with a work-clamp adapted to hold in a stretched condition the material having the buttonhole to be stitched, means to move the said clamp stitch after stitch; a needle-bar, an attached needle, actuating mechanism for said needle-bar, a complementary under-thread carrier; a throat-plate, a vertically-movable rod to the upper end of which said throat-plate is secured, means to reciprocate said rod to lower and raise the throat-plate, the said throat-plate being lowered while the needle is out of the material and the work-clamp is being moved to feed the material, and being raised while the needle is in the material.

42. In a buttonhole-sewing machine, the following instrumentalities, viz: stitch-forming mechanism; a work-clamp to hold in stretched condition the material containing the buttonhole to be stitched, means to move said clamp intermittently to enable the stitching to be made about the sides of the buttonhole; a throat-plate located below the work-clamp and having holes to receive and guide a cord; and means to raise and lower said throat-plate.

43. In a buttonhole-sewing machine, overedge-stitch-forming mechanism, a clamp to hold the material, and means to change the relative positions of said stitch-forming means, and work-clamp, during the stitching of a buttonhole; combined with a vertically-movable anvil arranged below said clamp; a cutter-carrier, having an attached cutter; and actuating devices for said cutter-carrier, said actuating devices having means to act on and move said anvil against the under side of the material held in the clamp during the descent of the cutter-carrier.

44. In a buttonhole-sewing machine, stitch-forming mechanism, a rotatable carrier having a plurality of notches, a plurality of dogs mounted on said carrier, locking means to enter said notches one after the other in the formation of a buttonhole to restrain at each times the rotation of the carrier, a work-clamp slidably mounted in said carrier, and a device to engage and then retire from one of said dogs after the other to effect partial rotation of the carrier and work-clamp while stitching about the ends of a buttonhole, partial rotation of the carrier and clamp taking place after stitching each straight side of the buttonhole.

45. A work-clamp, stitch-forming mechanism to form a series of overedge-stitches about the edge of a buttonhole, a work-clamp to hold the material containing said buttonhole, a rotating work-clamp-actuating cam-ring having a too D' and a groove provided with an open space 57 and projections 55 and 56 in said groove, and having a lug 54 crossing a part of said groove, a raceway-plate having openings O' and a notch 125, a circular carrier open at its center to receive and guide the work-clamp that it may be slid therein, said carrier having at its edge a plurality of notches and a plurality of pivoted dogs, each dog having at its under side a projection to enter the groove of said cam-ring, a projection O' acting normally against the edge of said carrier and adapted to enter one or the other of the notches in the edge of said carrier when the said notches come opposite said projection, the too D' forcing the projection from one and the other of said notches at the desired times.

46. In a buttonhole-stitching machine, stitch-forming mechanism to make a series of overedge-stitches about the entire edge of a buttonhole, a work-clamp, means to move the clamp while the edge of the buttonhole is being overstitched, a clutch in operative engagement with a shaft for operating the stitch-forming mechanism to make stitches, device made operative immediately after the completion of the overedge-stitching to move said clutch and stop the stitching, and automatically-controlled means to thereafter further move said work-clamp at a faster speed into its starting position.

47. In a machine for stitching buttonholes, overedge-stitch-forming mechanism, a cloth-clamp to grasp between its members and hold the material to be overstitched, a plate on which the base of said clamp is pivoted, means to move said plate and clamp longitudinally during the stitching of the edges of the buttonhole, and means to move one end of said clamp laterally on said movable plate during the stitching of the enlarged eye of the buttonhole.

48. In a machine for stitching buttonholes, overedge-stitch-forming mechanism, a cloth-clamp, means for giving a relative rotary movement to the said stitch-forming mechanism and cloth-clamp during the overedge-stitching of both ends of the buttonhole, means to move said clamp longitudinally during the overstitching of the edges of the buttonhole, and means to move one end of said clamp laterally during the stitching of the enlarged eye of the buttonhole.

49. In a machine for stitching buttonholes, stitch-forming mechanism, a work-clamp, buttonhole-cutting mechanism, means to start the cutting mechanism into operation to cut the material held in the clamp, and means controlled by the cutting mechanism to start automatically the stitch-forming mechanism into operation after the completion of the cutting operation.

50. In a buttonhole-stitching machine, a cloth-clamp, means to sustain it, a cutter located above the cloth-clamp, means to carry the cutter, stitch-forming mechanism to make an overedge-stitch, a throat-plate, an anvil, and means to move the throat-plate and anvil each into and out of contact with the under side of the material held in the clamp, the anvil occupying its operative level under the material held by the clamp only when the material is to be cut preparatory to stitching the same, the throat-plate being moved into its operative position to contact with the material only when the stitch-forming mechanism is operating to overstitch the edge of the buttonhole.

51. In a buttonhole-stitching machine, stitch-forming mechanism to form overedge-stitches, a cloth-clamp to hold the material to be stitched, means to change the relative position of said stitch-forming mechanism and cloth-clamp to enable stitches to be formed about the edges of a buttonhole-end, a vertically-movable cutter, and an anvil, both occupying normally inoperative positions out of contact with the material held by the clamp, means to move vertically automatically said anvil into its operative position to contact with the material held by the clamp, and move said cutter to contact with said anvil and cut the material held in the clamp, and means to thereafter restore said cutter and anvil to their inoperative

position and maintain them in each position until again to be actuated to cut the material for another buttonhole.

52. In a machine for stitching buttonholes, stitch-forming mechanism to form overedge-stitches, a work-clamp to hold the material to be cut and stitched, means to change the relative positions of said stitch-forming mechanism and work-clamp to effect the stitching of the edge of a buttonhole, buttonhole-cutting mechanism comprising a blade and an anvil, each occupying normally their inoperative positions out of contact with the material, a shaft, connections between said shaft and cutting mechanism, a continuously-moving pulley, means to couple said pulley with said shaft whereby the same is started and the anvil put in its operative position next the under side of the material held in said clamp, and the cutter actuated to cut the material resting above said anvil.

53. In a buttonhole-stitching machine, stitch-forming mechanism, a cloth-clamp to receive the material to be cut and stitched, buttonhole-cutting mechanism, a shaft sustained outside the frame carrying the stitch-forming mechanism, said shaft actuating said cutting mechanism, manually-controlled means for causing the cutting mechanism to act and cut the material in the clamp and return the buttonhole-cutting mechanism into its inoperative position, and automatically-actuated means to start into operation the stitch-forming means after the buttonhole-cutting means has been operated.

54. In a buttonhole-stitching machine, stitch-forming mechanism, a cloth-clamp to receive the material to be cut and stitched, buttonhole-cutting mechanism, an independent shaft located below the bench containing the stitching mechanism, means independent of the stitching mechanism for operating said shaft, and manually-controlled means to cause the buttonhole-cutting mechanism to act but once, and then come to a position of rest.

55. In a machine for stitching buttonholes, stitch-forming mechanism, means to actuate the same to form overedge-stitches, means to sustain the stitch-forming mechanism, a work-clamp to hold the material, means to change the relative positions of the work-clamp and the means sustaining the stitch-forming mechanism, whereby overedge-stitches are made about the edge of the buttonhole, means to stop automatically the action of the stitch-forming mechanism when the buttonhole has been fully stitched, and means, including a worm, a worm-gear, and a shaft having a toothed wheel to thereafter continue automatically the relative change of position of said work-clamp and the means sustaining the stitch-forming mechanism until the work-clamp and the means for sustaining the stitch-forming mechanism occupy their positions in which the work is removed from and other work applied to the work-clamp.

56. In a machine for stitching buttonholes, stitch-forming mechanism, means to sustain the same, means to actuate the stitch-forming mechanism to form overedge-stitches, buttonhole-cutting mechanism, a work-clamp to receive the material, means to actuate the buttonhole-cutting mechanism to cut the material in the clamp, means to start into operation the stitch-forming mechanism, means to change the relative positions of the work-clamp, and means for sustaining the stitch-forming mechanism that the stitch-forming mechanism may stitch fully about the edge of the slit cut in the material, means to stop the stitching action of the stitch-forming mechanism when the said slit has been over stitched, and means to continue at a faster speed the relative change of position of said work-clamp, and means for sustaining the stitch-forming mechanism while the stitch-forming mechanism is inactive as to making stitches until the said work-clamp and means for sustaining the stitch-forming mechanism again occupy the position in which the work may be removed from the clamp and other work inserted in the clamp.

57. In a buttonhole-stitching machine, stitch-forming mechanism, a work-clamp adapted to hold stretched the material in which the buttonhole is being stitched throughout the stitching operation, means to change the relative positions of said work-clamp and stitch-forming mechanism while making overedge-stitches about the edge of the buttonhole-slit, combined with a throat-plate normally supporting the material within the open central portion of said closed clamp while the needle is penetrating the material, and means to lower said throat-plate from contact with the material while the needle is out of the material.

696,699. BUTTONHOLE-STITCHING MACHINE. ROBERT W. THOMSON, Lynn, Mass., assignor to Essex Buttonhole Machine Company, Boston, Mass., a Corporation of Maine. Original application filed Jan. 20, 1902, Serial No. 418,678. Divided and this application filed Aug. 8, 1901. Serial No. 70,889. (No model.)

Claim.—1. The combination with upper and under needles of a buttonhole-stitching machine, and actuating means thereof, of a loop-spreader, a movable bearing sustaining the chuck of said spreader, means to impart a lateral movement to the loop-spreader bearing, and means to impart a relative movement to the loop-spreader in its bearing in the formation of a buttonhole-stitch.

2. In a buttonhole-stitching machine, a cloth-clamp to hold the material to be stitched, stitch-forming mechanism including an upper and an under thread carrying needle, a loop-spreader having a shaft, a bearing for said shaft, means to impart at the proper time a rotary movement to said loop-spreader, and means to move said bearing and loop-spreader bodily that the spreader may take the loop of upper thread and spread said loop for the entrance of the needle carrying the under thread as the latter rises past the edge to be over stitched.

3. In a machine for stitching buttonholes, a work-clamp to hold the material to be stitched, an eye-pointed upper-thread-carrying needle to penetrate the material back from its edge to be over stitched, means to actuate said needle for stitching, a curved under-thread-carrying needle located below the material, a pivoted carrier for said curved needle, a link connected with said curved-needle carrier, a lever connected with said link, an eccentric-strap, means to move it, and a ball connection between said eccentric-strap and lever.

4. In a buttonhole-stitching machine, the combination with an eye-pointed needle and an under-thread-carrying needle, of a bearing pivoted near one end, a loop-spreader having its shaft mounted in said bearing, means to swing said bearing about its pivot, and means to rotate said shaft in said bearing, whereby said spreader while being rotated in the bearing may have a bodily lateral movement given to its shaft.

5. In a buttonhole-stitching machine, the following instrumentalities, viz: a needle-bar having a needle to carry an upper thread, actuating means therefor, a vertical shaft provided with a loop-spreader, a pivoted bearing in which the shaft of said spreader is mounted, an under-thread carrier, means to actuate the under-thread carrier to move it across the edge of the material to be over stitched, and means to move said bearing with the spreader-shaft and spreader laterally to thereby remove the spreader quickly out of the path of the ascending under-thread carrier.

6. In a buttonhole-stitching machine, a needle-bar having an eye-pointed upper-thread-carrying needle, a bearing to sustain said needle-bar, means to reciprocate said needle-bar in said bearing, an under-thread-carrier adapted to carry a thread through the buttonhole and prevent it under the descending needle, and means to adjust said bearing and maintain it in adjusted position, that the needle may penetrate the material back from the edge of the slit for the desired distance to insure the desired width of overedge-stitch, as may be required.

7. In a buttonhole-stitching machine, a work-clamp, a needle-thread, a vertically-arranged needle-bar having an eye-pointed needle, a horizontally-arranged shaft having a connected under-thread carrier, arms supporting said shaft, pivots sustained in a stationary part of the frame of the machine, located near the level of the under side of the material to be held in the work-clamp, and means for actuating said shaft that the under-thread carrier, as it rises to interlock its thread with the needle-thread, will rise through the slit in the material in substantially a vertical line, thereby obviating straining the material in the direction of the width of the buttonhole-slit.

696,700. VEHICLE-TIRE. FREDERICK TILLMANT, SAN FRANCISCO, Cal., assigner, by direct and mesne assignments, to Tillmanti Steel Tube Tire Company, a Corporation of California. Filed July 5, 1901. Serial No. 67,941. (No model.)

Claim.—1. A vehicle-tire or the like consisting of a single metal tube formed with a male and a female end, a spring at one end of said tube and a depression in the opposite end, said spring being adapted to engage said depression and hold said ends together, for the purpose set forth.

2. A vehicle-tire or the like consisting of a single metal tube formed with a male and a female end, a continuous depressed portion extending the entire length of said tire, and a compressed-leather strip secured in said depressed portion and forming a non-slipping tractional surface for said tire, substantially as and for the purpose set forth.

696,701. FURNACE. WILLIAM WARELY, Taunton, Mass. Filed Dec. 7, 1901. Serial No. 66,664. (No model.)

Claim.—1. In a furnace of the character described, the combination with a combustion-chamber, an outlet therefor, and an intermediate passage downwardly inclined from the combustion-chamber to said outlet, of a plurality of substantially narrow deep basins or receptacles formed in the hearth of the furnace with the basin remote from the combustion-chamber at a lower level than the one adjacent to said combustion-chamber, the said basins being extended transversely of the furnace and separated by a portion of the hearth of substantial thickness and having its surface of such inclination as to direct the flame passing over the lower basin to substantially the longitudinal center of the said basin, substantially as described.

2. In a furnace of the character described, the combination with a combustion-chamber, a downwardly-inclined passage communicating therewith, and an outlet port or opening communicating with said passage, of a plurality of basins or pockets curved in cross-sections and extended across said furnace below said inclined passage and having outlet-openings communicating with the exterior of the furnace, said basins or pockets being located at different levels with the basin remote from the combustion-chamber at a lower level than the basin adjacent to the combustion-chamber, substantially as and for the purpose specified.

3. In a furnace of the character described, the combination with a

combustion-chamber, an outlet therefor and an intermediate passage connecting the same, of a plurality of basins located in the hearth of the furnace between said combustion-chamber and said outlet, the more remote basin being located at a lower level than the basin adjacent to said combustion-chamber, and a removable cover for said remote basin, substantially as and for the purpose specified.

696,702. ELECTRIC-HOSE COUPLING. GEORGE C. WITZ, Medford, Mass., assigner to himself and Franklin K. Young and Michael P. O'NEILL, trustees, Boston, Mass. Filed Jan. 24, 1902. Serial No. 61,132. (No model.)

Claim.—1. A female member of a coupling for electric hose having a shell with an interior flange, an insulating-ring within said shell and butting against the flange of said shell, a contact-ring set in said insulating-ring and insulated thereby from the shell, said contact-ring having one or more contact-fingers projecting longitudinally therefrom, substantially as described.

2. A female member of a coupling for electric hose having a shell with an interior flange, a flanged insulating-ring within said shell and butting against the flange of said shell, a contact-ring within the mouth of said insulating-ring and butting against the flange thereof, and insulated from said shell, said contact-ring having one or more contact-fingers projecting longitudinally outward therefrom, the inner periphery of the contact-ring, insulating-ring and said shell-flange forming a flush waterway, and a wire electrically connected with said contact-ring and an insulated passage for said wire through the flange of the shell to the hose, substantially as described.

3. A female member of a coupling for electric hose having a shell with an interior flange, a flanged insulating-ring butting against said flange, a contact-ring in the mouth of said insulating-ring butting against the flange thereof which insulates it from the shell, an insulating-gasket against the outer ends of the contact-ring and the insulating-ring, contact-fingers projecting outward from said contact-ring and a wire electrically connected with said contact-ring and leading rearwardly therefrom through the flange of the shell from which it is insulated and through the hose, substantially as described.

4. A female member of a coupling for electric hose having a shell with an interior flange, a flanged insulating-ring butting against said flange, a contact-ring in the mouth of said insulating-ring butting against the flange thereof and insulated thereby from the shell, an insulating-gasket against the outer ends of the contact-ring and the insulating-ring, contact-fingers projecting from said contact-ring, a wire leading from said contact-ring rearwardly through the flange of the shell and coiled around in a coil in said flange, and insulated from said flange, and a gasket on the rear face of said flange which holds the wire on its seat, the wire leading from the coil through the said gasket and back through the hose, substantially as described.

5. A female member of a coupling for electric hose having a shell with an interior flange, a flanged insulating-ring against said flange, a contact-ring in the mouth of said insulating-ring against the flange thereof and insulated from said shell, an insulating-gasket against the outer ends of said contact-ring, contact-fingers projecting from said contact-ring, a wire connected with said contact-ring and insulated from the shell and leading through the hose, in combination with a male member having a contact-ring with which a wire is connected, said wire and contact-ring being insulated from the body of the shell, said contact-ring making contact with the fingers on the contact-ring of the female coupling when the two members are coupled, substantially as described.

696,708. HAND-POWER PROPELLER. ISAAS A. WILSON, Detroit, Mich. Filed Apr. 16, 1901. Serial No. 94,143. (No model.)

Claim.—1. A propeller vessel comprising in its construction a hull, parallel side timbers carried thereby and provided with grooves, a framework mounted upon the said timbers adapted to engage such grooves, and means for operating propelling mechanism supported by said framework, the construction and arrangement being such that the said framework may be moved longitudinally of the said side timbers, and carry with it said propeller-operating mechanism substantially as described.

2. A propeller vessel comprising in its construction a hull, parallel side timbers mounted therein and provided with longitudinal grooves, a framework slidably mounted upon said timbers, means carried by said framework engaging said grooves, stern and side propeller-operating mechanism mounted upon said framework, and means for operating such mechanism, substantially as described.

3. A propeller vessel comprising in its construction a hull, a framework slidably mounted therein, and means mounted on said framework for simultaneously operating stern-screw and side-propeller mechanism, substantially as described.

4. A propeller vessel comprising in its construction a hull, a framework mounted therein and slidably longitudinally thereof, and hand-operated means carried by said framework for simultaneously actuating stern-screw and side-propeller mechanism, substantially as described.

5. In a hand-operated-propeller vessel, the combination with a hull of a framework slidably mounted within the same, a crank-shaft finding bearings in said framework arranged transversely of the said hull and having its ends extending beyond the sides thereof and adapted to carry side-wheel propellers, a crank interposed intermediate the length of said shaft, hand-operated means for rotating the said crank, and means carried by said crank-shaft for imparting motion to a stern-propeller, substantially as described.

6. In a hand-operated-propeller vessel, the combination with a hull of means for operating a stern-propeller, comprising a framework mounted within said hull, a crank-shaft arranged transversely of the said framework and finding bearings thereon, a crank mounted upon the said shaft, hand-operated means for rotating the same, a beveled gear-wheel rigidly

affixed to said shaft, a counter-shaft extending at right angles to said crank-shaft and carrying a pinion adapted to mesh with the said beveled gear-wheel, a spur-wheel carried by the opposite end of said counter-shaft, a main shaft extending longitudinally of said hull and carrying a pinion adapted to mesh with the said spur-wheel, a shaft extending from the stern of said hull and carrying a screw-propeller at its outer end, and flexible means connecting said propeller-shaft with said main shaft, substantially as described.

7. In a hand-operated-propeller vessel, the combination with a hull, of means for operating a stern-propeller, comprising a framework slidably mounted within said hull, a crank-shaft arranged transversely of said framework and finding bearings thereon, hand-operated means for rotating the same, a beveled gear-wheel affixed to said shaft, a counter-shaft extending at right angles thereto and carrying a pinion adapted to mesh with the said beveled gear-wheel, a spur-wheel carried by said counter-shaft, a main shaft arranged longitudinally of said hull and provided with a groove for a portion of its length, a pinion keyed to said grooved portion and slidably longitudinally of said shaft and adapted to mesh with said spur-wheel, and means for imparting motion from said main shaft to a screw-propeller at the stern of said hull, the construction and arrangement being such that the said framework together with its supported propeller-operating mechanism may be adjusted bodily longitudinally of said hull for raising or lowering the stern thereof, substantially as described.

8. In a hand-operated-propeller vessel, the combination with a hull, of a framework mounted therein, a crank-shaft extending transversely of said framework, means carried by said crank-shaft for imparting motion simultaneously to stern and side propeller-wheels, a crank mounted upon said shaft, and hand-operated means for rotating the same, comprising a yoke having its ends pivotally secured to said hull and its arched portion extending upwardly therefrom and adapted to serve as a handle, a cross-rod connecting the arms of said yoke, a pitman pivotally secured to said cross-rod and connecting the same with said crank, and means for adjusting said cross-rod longitudinally of said yoke, substantially as described.

9. In a hand-operated-propeller vessel, the combination with the hull, of crank-operated mechanism for imparting motion to stern and side propellers, and means for rotating said crank comprising a yoke having its ends pivotally secured to said hull, means for adjusting said ends longitudinally of the hull, sleeve-bearings carried by the arms of said yoke, means for adjustably securing said sleeves at varying distances longitudinally of said arms, a rod connecting said sleeve-bearings, and a pitman connecting the said rod with said crank, substantially as described.

10. In a hand-operated-propeller vessel, the combination with a hull, of crank-operated mechanism therein for imparting motion to a suitable propeller, and means for rotating said crank, comprising a yoke having its ends pivotally secured to said hull, means for adjusting the ends thereof longitudinally of said hull, a rod connecting the arms of said yoke, means for adjusting the said rod longitudinally thereof, and a pitman pivotally secured to said rod and connecting the same to said crank, substantially as described.

696,704. DRIVING-GEAR. CHARLES F. ALLEN, Humboldt, Cal., assignor of one-half to L. R. Hague and W. C. Hewitt, Santa Paula, Cal. Filed Aug. 4, 1900. Serial No. 28,947. (No model.)

Claim.—1. The combination with an axle formed of two similar sections; of a pin loosely mounted within the adjacent end of said sec-

tions, a beveled pinion secured to each section near the inner end thereof, a sleeve loosely mounted upon the sections between the pinions, pins detachably secured to the sleeve and formed with projecting flattened heads, a gear mounted upon each pin and engaging both pinions, a toothed ring secured to the heads of the pins and surrounding the axle, and collars secured to opposite sides of the ring and enclosing the pinions.

2. The combination with an axle formed of two similar sections; of a pin loosely mounted within the adjacent ends of the sections, a beveled pinion secured to each axle-section near the inner end thereof, a sleeve loosely mounted upon the sections and between the beveled pinions, pins extending from and detachably secured to the sleeve and having projecting flattened heads, gears mounted upon the pins and engaging both pinions of the axle, a gear formed of two similar rings secured to the heads of the pins and surrounding the axle, and a collar secured to each ring and enclosing the pinions, one of said collars having a grooved periphery.

3. The combination with an axle formed of two similar sections; of a pin loosely mounted within the adjacent ends of said sections, a pinion secured to each section near the inner end thereof, a sleeve loosely mounted upon the sections between the pinions, pins detachably secured to and extending from said sleeve, a gear mounted upon each pin and engaging both pinions, each pin having a flattened head, a sectional toothed ring having on the inner face of each section a recess for the reception of said heads, said ring formed of two similar rings, collars at opposite sides of the toothed ring and enclosing the pinions, and means for binding the collars, the rings, and the heads of the pins together.

696,705. COMBINATION CASE AND WHIP. MARY A. ALLEN, Fitzgerald, Ga. Filed Oct. 22, 1901. Serial No. 78,731. (No model.)

Claim.—1. A combination case and whip comprising a hollow, cylindrical casing provided with internal and external screw-threads at its upper end, and internal screw-threads at its lower end, a whip provided at its lower end with an externally-screw-threaded butt adapted to fit in the threaded lower and upper ends of the casing as the device is used for a case and whip respectively, and an internally-screw-threaded handle to engage the external threads of the casing.

2. A combination case and whip comprising a hollow screw-threaded casing, a removable handle therefor, a whip formed of hinged sections adapted to be folded and inserted within the casing, a sliding sleeve for securing the whip-sections in their unfolded position, and a catch device for engaging the whip-link.

3. A combination case and whip comprising a hollow cylindrical casing provided with both internal and external screw-threads at its upper end, a whip consisting of jointed sections one of which is screw-

threaded to engage the internal threads of the casing, a sliding sleeve to secure the whip-sections in unfolded position, and an internally-threaded handle to engage the external threads of the casing.

4. A combination case and whip comprising a hollow cylindrical casing provided with internal and external screw-threads at its upper end, and internal screw-threads at its lower end, a whip consisting of sections provided at their meeting ends with sleeves slotted to receive a coupling-link whereby said sections are joined, a sliding sleeve to secure the whip-sections in unfolded position, a butt-end externally screw-threaded and provided with a lug to form a ferrule when the whip is converted into a cane, and an internally-threaded handle to engage the external threads of the casing.

696,706. ELEVATOR. CYRUS W. BALDWIN, Yonkers, N. Y. Mary E. Baldwin, administratrix of said Cyrus W. Baldwin, deceased, assignor to the Otis Elevator Company, East Orange, N. J., a Corporation of New Jersey. Filed Dec. 27, 1904. Serial No. 553,082. (No model.)

Claim.—1. The combination with an elevator-cage, of a receptacle open at the top and arranged near the end of the well, and a valveless counterbalance-weight securing the receptacle and loosely fitting the same, substantially as described.

2. The combination of an elevator-cage, a water-tank upon the cage, a valve, and automatic means whereby the valve is operated to discharge water from the tank in proportion to the weight of the passengers in the cage, substantially as set forth.

3. The combination of a cage, a tank carried thereby, a valve controlling the discharge of water from the said tank, and automatic apparatus carried by the cage and connected with the valve to shift the latter according to the weight in the cage, substantially as set forth.

4. The combination of an elevator-cage, a movable platform in the cage, a tank carried by the cage, and a discharge-valve connected operatively to the movable platform, substantially as set forth.

5. The combination of an elevator-cage, a tank, a tubular discharge-valve, a movable platform, and connecting devices whereby the valve is lowered in proportion to the extent to which the platform descends, substantially as set forth.

6. The combination of an elevator-cage, a tank, a discharge-valve, a platform connected to operate the latter, and an indicator connected with the platform, substantially as set forth.

7. The combination of an elevator-cage, a tank, a platform, a discharge-valve connected therewith, supports for supporting the platform movably within the cage, and means for adjusting the said supports, substantially as described.

696,707. COFFIN-PROTECTOR. SAMUEL L. BLACK and HOLLIS P. BUNKER, Columbus, Ohio. Filed Aug. 13, 1901. Serial No. 73,863. (No model.)

Claim.—1. In a coffin-protector, a bottom frame, lock-cases thereon having automatically-operative bolts therein, and a top or protecting frame composed of horizontal bars with downwardly-bent legs integral with said bars whereby said legs can be simultaneously inserted and locked in said lock-cases.

2. In a coffin-protector, a bottom frame composed of bars having stops at their ends, lock-cases adapted to be placed on said bars beyond such stops, and a top or protecting frame having downwardly-extending legs integral with such top frame to enter and be secured in such lock-cases.

3. In a coffin-protector, a bottom frame, anchoring-bolts therefor extending below said frame, lock-cases on the bottom frame, and a top or protecting frame having legs integral therewith to enter and be secured in said lock-cases.

4. In a coffin-protector, a top or protecting frame adapted to be supported and secured above the top of the coffin, and an earth-supporting shield adapted to be suspended from said protecting-frame, but below the top frame.

5. In a coffin-protector, a top or protecting frame adapted to be supported above the top of the coffin, and an earth-supporting shield composed of lapping sections with means for suspending such sections from the protecting-frame, substantially as described.

6. In a coffin-protector, a top or protecting frame adapted to be supported above the top of the coffin, and an earth-supporting shield composed of lapping sections adjustable upon each other, with means for suspending such sections from the protecting-frame, substantially as described.

7. In a coffin-protector, a bottom frame, and a top or protecting frame having downwardly-extending recessed legs, and a lock-case to receive such leg having an automatically-operative bolt formed to enter a recess in the leg and bridge squarely the space between the leg and lock-case for the purpose explained.

8. In a coffin-protector, a bottom frame composed of longitudinal and cross bars having downwardly-turned ends to form hooks, lock-cases perforated horizontally to be placed on said hooked ends and recessed vertically and provided with automatic catches, a top or protecting frame composed of longitudinal and cross bars having downwardly-bent ends to enter and be secured by the automatic catches in the lock-cases, and means for anchoring the bottom frame, substantially as described.

696,708. MACHINE FOR COPYING PATTERNS FOR JACQUARD-CARDS. JOHN T. BOLTON, Fall River, Mass., assignor of one-fourth to Thomas McAniff, Fall River, Mass. Filed Jan. 6, 1902. Serial No. 83,568. (No model.)

Claim.—1. The combination of a board to hold a design-pattern, having screw-shafts held in bearings attached to the upper and lower edges, a vertical shaft held in bearings at the side of the board and connected by bevel-gears with said screw-shafts, a case to slide on said bar, a solenium-coil held on said case, a screw held in bearings on said bar, a nut on said screw attached to the case, a relay-battery, electrical connection between said case and the relay-battery, substantially as described.

2. The combination of a pattern, a case to pass over said pattern, mechanism to move said case over the pattern, a punching-machine operated by said mechanism synchronously with said case, a relay-battery to designate what punches shall be operated by said mechanism, a solenium-coil to control said relay-battery, substantially as described.

3. The combination of a solenium-coil, a design-pattern, mechanism for passing said coil over the design-pattern, a relay-battery, wires to connect said solenium-coil and relay-battery, a punching-machine connected by said wires to the relay-battery, means for connecting said punching-machine with the mechanism that moves the solenium-coil over the design-pattern, substantially as described.

4. The combination of two end frames, a series of punches and dies, feed-rolls, a series of dogs held spirally on a shaft over said punches, a main shaft, means for turning and raising and lowering said dogs, an electromagnet to control the dropping of the punches, a relay-battery to energize the electromagnet, a board to hold a design-pattern, mechanism connected with said board to control the relay-battery according to the design-pattern, substantially as described.

696,709. PROCESS OF MAKING CONDUIT OUTLET-BOXES. WILLIAM F. BUNKER, Utica, N. Y., assignor to the Bunker Electric Construction Company, Utica, N. Y. Filed Sept. 16, 1901. Serial No. 75,054. (No specimens.)

Claim.—1. The herein-described process of forming an outlet-box for interior conduits from a thin flat plate of ductile metal, which consists in first forming the plate with a depressed central portion and an outwardly-curved marginal flange, then bending up portions of said flange while holding other portions outwardly bent to form ears, and then grinding off said upwardly-bent portions.

2. The herein-described process of forming an outlet-box for interior conduits from a thin flat plate of ductile metal, which consists in first forming the plate with a depressed central portion and an outwardly-curved marginal flange, then bending up portions of said flange while holding other portions outwardly bent to form ears, then grinding off said upwardly-bent portions, and then bending the ears upward to the plane of the sides of the box.

696,710. INTERIOR-CONDUIT OUTLET-BOX. WILLIAM F. BUNKER, Utica, N. Y., assignor to the Bunker Electric Construction Company, Utica, N. Y. Original application filed Sept. 16, 1901. Serial No. 75,054. Divided and this application filed Jan. 17, 1902. Serial No. 90,140. (No model.)

Claim.—1. An outlet-box cover comprising a flat plate having a central opening with an upturned flange, and a plurality of parallel slots near the edge of the plate.

2. An outlet-box having its walls substantially at right angles to its bottom and provided with two or more perforated ears extending in the

same plane as the said walls; with a bodily-removable cover having slots to receive the said ears secured to the box by pins.

2. An outlet-box having its walls substantially at right angles to its bottom and provided with two or more perforated ears extending in the same plane as the said walls; with a bodily-removable cover having slots to receive the said ears and an opening in its central part, secured to the box by outer-pins.

3. An outlet-box struck or drawn up from a single piece of ductile metal, provided with two or more integral ears extending in the same plane as the walls thereof, the edges of the walls being ground off smooth, as set forth.

4. An outlet-box struck or drawn up from a single piece of ductile metal, provided with two or more integral ears extending in the same plane as the walls thereof, the edges of the walls being ground off smooth, as set forth.

5. The combination of an outlet-box struck or drawn up from a single piece of ductile metal, provided with two or more integral ears extending in the same plane as the walls thereof, the edges of the walls being ground off smooth, and the ears having perforations; a cover made from a single piece of metal having slots adapted to fit over the ears of the box; with spring or outer pins for the perforations of the ears, as set forth.

6. An outlet-box struck or drawn up from a single piece of ductile metal, provided with two or more integral ears extending in the same plane as the walls thereof, the edges of the walls being ground off smooth, and the ears having perforations.

7. An outlet-box struck or drawn up from a single piece of ductile metal, provided with two or more integral ears extending in the same plane as the walls thereof, the edges of the walls being ground off smooth, and the ears having perforations.

696,711. FIRE-ESCAPE. THOMAS J. BRINER, Reading, Pa. Filed Dec. 26, 1901. Serial No. 87,857. (No model.)

Claim.—In a fire-escape, a vertical hollow rod securely held at its top and bottom ends, having a pulley near its upper end and an opening therein in front of said pulley, a weight traveling inside said rod, a flexible handpiece controlling said rod adapted to ride up and down thereon, and attached to said weight by a flexible cord passing over said pulley, and a pivoted footpiece, depending from and connected to said handpiece and controlling said rod and having roughened inner surfaces capable of being forced against the outer surface of said rod by the weight of the operator, substantially as and for the purpose set forth.

696,712. SHOE-POLISHER. JOHN F. BACCHINI, New York, N. Y. Filed Dec. 20, 1901. Serial No. 87,908. (No model.)

Claim.—1. A shoe-polisher comprising an oblong block having its under side surface cut out longitudinally, and provided with a flexible polishing-strip which is stretched longitudinally of the bottom thereof and the ends of which are folded upwardly over the ends of said block, and

spring-clamps provided with angular arms which are pivoted to the sides of said block near each end thereof, and the body portion of which extends across the top of said block, the arms of said clamps being provided each with a hole or opening, and fastening devices secured in the sides of said block and provided with heads adapted to enter said holes or openings, substantially as shown and described.

2. A shoe-polisher comprising an oblong block having its under side surface cut out longitudinally, and provided with a flexible polishing-strip which is stretched longitudinally of the bottom thereof and the ends of which are folded upwardly over the ends of said block, and spring-clamps provided with angular arms which are pivoted to the sides of said block near each end thereof, and the body portion of which extends across the top of said block, the arms of said clamps being provided each with a hole or opening and fastening devices secured in the sides of said block and provided with heads adapted to enter said holes or openings, the body portions of said clamps being flat in cross-section and the inner edges thereof being provided with downwardly-directed teeth, substantially as shown and described.

3. A shoe-polisher comprising an oblong block having its under side surface cut out longitudinally, and provided with a flexible polishing-strip which is stretched longitudinally of the bottom thereof and the ends of which are folded upwardly over the ends of said block, and spring-clamps provided with angular arms which are pivoted to the sides of said block near each end thereof, and the body portion of which extends across the top of said block the arms of said clamps being provided each with a hole or opening and fastening devices secured in the sides of said block and provided with heads adapted to enter said holes or openings, the body portions of said clamps being flat in cross-section and the inner edges thereof being provided with downwardly-directed teeth, and the outer edges thereof being upwardly curved, substantially as shown and described.

696,713. DENTAL LAYER. JOHN J. BROWN, Mason, Mo. Filed Dec. 18, 1901. Serial No. 86,084. (No model.)

Claim.—1. In a machine of the class described, the combination of a frame, a table detachably mounted on the front of the frame and capable of also being mounted on the back of the latter and provided with a shaft having a pulley or wheel, a seat detachably mounted on the frame at the back thereof and adapted to be removed when the table is to be arranged at the back, cranks arranged at opposite sides of the machine, a large wheel or pulley, a belt connecting said wheel or pulleys, and gearing for communicating motion from the cranks to the large pulley or wheel.

2. In a machine of the class described, the combination of a frame provided at its front with an arm, a table having a depending shank or bar detachably secured to the arm, a shaft or spindle mounted on and carried by the table, a seat-supporting bracket, detachably secured to the back of the frame and adapted to be removed to permit the table to be applied at that point, a seat mounted on the bracket, cranks arranged at opposite sides of the frame, and gearing for communicating motion from the cranks to the shaft or spindle, substantially as described.

3. In a machine of the class described, the combination of a frame comprising front legs provided with a vertical stem, rear legs having a vertical stem, a top plate connecting the stem of the rear legs with the front legs, means for connecting the lower portions of the legs, a table

having a depending shank detachably secured to the arm of the front legs, a seat-supporting bracket detachably secured to the stem of the rear legs and having a seat-supporting bar, a seat secured to the latter, a shaft or spindle carried by the table, and means for driving the shaft or spindle, substantially as described.

4. In a machine of the class described, the combination of a frame comprising front legs provided with a vertical arm, rear legs having an upright stem at the top, a top piece connecting the stem with the front legs, the side bars connecting the lower portions of the legs and extended beyond the front legs and provided with bearings, and transverse braces connecting the legs, a shaft mounted in the bearings of the side bars, a large drive-pulley mounted on the shaft, a sprocket-wheel also mounted on the shaft, the sprocket-wheel 15 adjustably mounted on the side bars, a chain connecting the sprocket-wheel, cranks connected with the sprocket-wheel 15, a table mounted on the arm of the front legs, a shaft or spindle carried by the table and provided with a small pulley, a belt connecting the mid pulley, a seat-supporting bracket secured to the stem of the rear legs, and a seat mounted on the bracket, substantially as described.

696,714. VERTICAL-TUBE STEAM-ROLLER. FRANK BURGESS and HENRY M. WILLIAMS, Fort Wayne, Ind.; said Burgess assignor of one-half of his right to said Williams. Filed Oct. 22, 1902. Removed Aug. 1, 1903. Serial No. 70,500. (No model.)

Claim.—1. In a roller, two horizontally-disposed substantially cylindrical shells supported one above the other, their points of junction being connected by a perforated plate, substantially as described.

2. In a roller, two horizontally-disposed substantially cylindrical shells supported one above the other, and a fire-box inclosed in one of the shells, substantially as described.

3. In a roller, two horizontally-disposed substantially cylindrical shells supported one above the other, and a substantially cylindrical fire-box inclosed within the lower shell and connected thereto, substantially as described.

4. In a roller, two horizontally-disposed substantially cylindrical shells supported one above the other, a fire-box within one of the shells, and tubes extending from the fire-box to the top of the upper shell, substantially as described.

5. In a roller, two horizontally-disposed substantially cylindrical shells supported one above the other, a fire-box within one of the shells, a chamber above the other shell, and vertical tubes extending between the fire-box and chamber, substantially as described.

6. In a roller, two horizontally-disposed shells supported one above the other, a fire-box connected with one shell, a chamber connected with the other, and vertical tubes extending from the fire-box to said chamber, the chamber being provided with an opening and with means for controlling the opening, substantially as described.

7. In a roller, two horizontally-disposed shells supported one above the other, and vertical tubes extending from the fire-box to said chamber, the chamber being provided with an opening, binged wings, and means for operating them for controlling the opening, substantially as described.

8. In a roller having tubes extending to the outer surface thereof, a chamber inclosing the ends of said tubes, said chamber being provided with means for regulating the draft through the tubes into the chamber, substantially as described.

9. In a roller having tubes extending to the outer surface thereof, a

chamber inclosing the ends of said tubes, said chamber being provided with an opening and with means connected to air-chambers for controlling the draft through said tubes, substantially as described.

10. In a roller having tubes extending to the outer surface thereof, a chamber inclosing the ends of said tubes, said chamber being provided with an opening, pivoted wings controlling the opening, and means connected with the wings for adjusting their positions with relation to the opening, substantially as described.

11. In a roller, two horizontally-disposed substantially cylindrical shells supported one above the other, a plate interposed between their points of junction, a substantially cylindrical fire-box inclosed within one of the shells, a chamber supported upon the other shell, vertical tubes extending from the crown of the fire-box to the crown of the upper shell, and means for regulating the draft through said tubes into said chamber, substantially as described.

696,715. WIRELESS TELEGRAPHY. JOHN BERRY, Fort Lee, N. J. Filed Dec. 4, 1902. Serial No. 791,534. (No model.)

Claim.—1. In wireless telegraphy and the like, the combination of a collector-circuit having a number of discontinuous branches in parallel, discontinuous local circuits equal in number to the branches of the collector-circuit, imperfect electrical contacts equal in number to the said collector-circuit branches, and means for periodically including each contact first in a collector-circuit branch and then in a local circuit to complete said circuit, and said contacts being included in rotation in the collector and the local circuits and each in different local circuits and collector-circuit branches.

2. In wireless telegraphy and the like, the combination of a collector-circuit having three discontinuous branches, three discontinuous local circuits, three imperfect electrical contacts, and means for periodically including each contact first in a collector-circuit branch, then in a local circuit, and then disconnecting it altogether, whereby said circuits are completed, and said contacts being included each in different local circuits and in different branches of the collector-circuit and in rotation in said circuits.

3. In wireless telegraphy and the like, the combination of a collector-circuit having a number of discontinuous branches, discontinuous local circuits equal in number to the branches of the collector-circuit, imperfect electrical contacts equal in number to the said collector-circuit branches, and means for periodically including each contact first in a collector-circuit branch and then in a local circuit to complete said circuit, and said contacts being included in rotation in the collector branches and the local circuits and each in different branches and local circuits, with a circuit-operating relay for and in each of said local circuits.

4. In wireless telegraphy and the like, the combination of a collector-circuit having three discontinuous branches, three discontinuous local circuits, three imperfect electrical contacts, and means for periodically including each contact first in a collector-circuit branch, then in a local circuit, and then disconnecting it altogether, whereby said circuits are completed, and said contacts being included each in different branches of the collector-circuit and in rotation in said circuits, with a circuit-operating relay for and in each of said local circuits.

5. In wireless telegraphy and the like, the combination of a collector-circuit having discontinuous branches, discontinuous local circuits, imperfect electrical contacts equal in number to said collector-circuit branches, senders with segments of which said branches and local circuits connect, and trailers connected with said contacts and coacting with said senders to complete said collector-circuit first through one and then another of its branches, and to complete each local circuit after the completion of the collector-circuit through a corresponding branch thereof.

6. In wireless telegraphy and the like, the combination of a collector-circuit having three discontinuous branches, three discontinuous local circuits, three imperfect electrical contacts, six three-segment senders with two segments of each of which said branches and local circuits connect, and sender-trailers connected with said contacts to complete said collector-circuit first through one and then a second and then the third branch thereof and to complete each local circuit after the completion of the collector-circuit through a corresponding branch thereof.

7. In wireless telegraphy and the like, the combination of a collector-circuit having discontinuous branches, discontinuous local circuits, imperfect electrical contacts equal in number to said collector-circuit branches, senders with segments of which said branches and local circuits connect, and trailers connected with said contacts and coacting with said senders to complete said collector-circuit first through one and then another of its branches, with a circuit-operating relay for and in each of said local circuits.

8. In wireless telegraphy and the like, the combination of a collector-circuit having three discontinuous branches, three discontinuous local circuits, three imperfect electrical contacts, six three-segment senders with two segments of each of which said branches and local circuits connect, and sender-trailers connected with said contacts to complete the collector-circuit first through one and then a second and then the third branch thereof and to complete each local circuit after the completion of the collector-circuit through a corresponding branch, with a circuit-operating relay for and in each of said local circuits.

9. In wireless telegraphy and the like, the combination of a collector-circuit having discontinuous branches, discontinuous local circuits, imperfect electrical contacts equal in number to said collector-circuit branches, senders with segments of which said branches connect, trailers connected with said contacts and coacting with said senders to complete the collector-circuit first through one and then another of its branches, and then the corresponding local circuits, a relay for and in each of said local circuits, a sender having as many segments as there are relays, an electromagnetically-operated instrument, a battery, a trailer for the last-named sender, and circuit-completing connections including the said instrument, battery and trailer in series and connecting said segments of the last-named sender each with a different relay of the local circuits.

10. In wireless telegraphy and the like, the combination of a collector-circuit having three discontinuous branches, three discontinuous local circuits, three imperfect electrical contacts, six three-segment senders with two segments of each of which said branches and local circuits connect, and sender-trailers connected with said contacts to complete said collector-circuit first through one and then a second and then the third branch thereof and then to complete said local circuits, with a relay for and in each of said local circuits, a sender having as many segments as there are relays, an electromagnetically-operated instrument, a battery, a trailer for the last-named sender, and circuit-completing connections including the said instrument, battery and trailer in series and connecting said segments of the last-named sender each with a different relay of the local circuits.

11. In wireless telegraphy and the like, the combination of a collector-circuit having a number of discontinuous branches, discontinuous local circuits equal in number to the branches of the collector-circuit, imperfect electrical contacts equal in number to the said collector-circuit branches, means for periodically including each contact first in a collector-circuit branch; then in a local circuit to complete said circuit, and then disconnecting it, and said contacts being included in rotation in the collector and the local circuits and each in different collector-circuit branches and in different local circuits, a circuit-operating relay for and in each local circuit, means for restoring each contact to normal condition while or disconnected, a relay for and in each local circuit, a sender having as many segments as there are relays, an electromagnetically-operated instrument, a battery, a trailer for the last-named sender, and circuit-

completing connections including the said instrument battery and trailer in series and connecting said segments of the last-named sender each with a different relay of the local circuits.

12. In wireless telegraphy and the like, the combination of a collector-circuit having three discontinuous branches, three discontinuous local circuits, three imperfect electrical contacts, means for periodically including each contact first in a collector-circuit branch, then in a local circuit, and then disconnecting it altogether, whereby said circuits are completed, and said contacts being included each in different local circuits and in different branches of and in rotation in said circuit, a circuit-operating relay for and in each local circuit, means for restoring each contact to normal condition while or disconnected, a relay for and in each of said local circuits, a sender having as many segments as there are relays, an electromagnetically-operated instrument, a battery, a trailer for the last-named sender, and circuit-completing connections including the said instrument, battery and trailer in series and connecting said segments of the last-named sender each with a different relay of the local circuits.

13. In wireless telegraphy and the like, the combination of a collector-circuit having a number of discontinuous branches, discontinuous local circuits equal in number to the branches of the collector-circuit, imperfect electrical contacts equal in number to the said collector-circuit branches, and means for periodically including each contact first in a collector-circuit branch and then in a local circuit to complete said circuit, and said contacts being included in rotation in the collector branches and the local circuits and each in different branches and local circuits, with a circuit-operating relay for and in each of said local circuits, a line having a battery and a relay or sender therein, and means for connecting said line with said local-circuit relays one at a time in succession.

14. In wireless telegraphy and the like, the combination of a collector-circuit having three discontinuous branches, three discontinuous local circuits, three imperfect electrical contacts, and means for periodically including each contact first in a collector-circuit branch, then in a local circuit, and then disconnecting it altogether, whereby said circuits are completed, and said contacts being included each in different branches of the collector-circuit and in rotation in said circuits, with a circuit-operating relay for and in each of said local circuits, a line having a battery and a relay or sender therein, and means for connecting said line with said local-circuit relays one at a time in succession.

696,716. LEATHER-STRETCHING DEVICE. JOHN CALDWELL, Minneapolis, Minn., assignor to the W. & H. Nett Company, Minneapolis, Minn., a Corporation. Filed Mar. 26, 1902. Serial No. 10,135. (No model.)

Claim.—1. A leather-holder for a stretching-machine, consisting of a body provided with means for engaging the leather to hold it, in combination with a device for pivotally connecting the holder to a part of the stretching mechanism, said holder being provided with means for varying the point of its pivotal connection to the connecting device conformably to the direction of tension of the leather, substantially as set forth.

2. A leather-holder for a stretching-machine, consisting of a body provided with means for engaging the leather to hold it and having in rear thereof a slot removed in the direction of the leather-engaging means, and a device adapted to engage in said slot and thereby pivotally connect the body to the stretching mechanism, substantially as set forth.

3. A leather-holder for a stretching-machine, comprising a body provided on its front portion with means for engaging the leather and in its rear portion with a slot removed toward the leather-engaging means, and a coupling device loosely pivoted thereto in each slot and permitting said body to turn freely in lateral direction with respect to the coupling device under tension, the coupling device having means for making adjustable connection with a stretching-machine, substantially as set forth.

4. A leather-holder for a stretching-machine, comprising a body provided with means for engaging the leather, and a coupling device loosely connected thereto and permitting free swiveling movement and lateral self-adjustment of said body with respect to the coupling device under tension, and means for adjustably connecting the coupling device to a part of the stretching mechanism, substantially as set forth.

5. A leather-holder for a stretching-machine, consisting of a body provided with means for pivoting the leather to hold it, in combination with a device for pivotally connecting the holder to a part of the stretching mechanism, said holder being provided with means for varying the point of its pivotal connection to the connecting device conformably to the direction of tension exerted upon the portion of leather engaged, substantially as set forth.

6. In a leather-stretching machine, the combination with a stretcher-head, of an independent leather-holder comprising a body provided with means for engaging the leather and having a slot concealed toward the leather-engaging means, and an inflexible coupling device loosely pivoted to each body in such slot and permitting it to turn freely thereon and adjust itself laterally with respect thereto under tension, and means whereby the coupling device may be adjusted laterally and longitudinally upon and connected to the stretcher-head, substantially as set forth.

7. In a leather-stretching machine, the combination with a stretcher-frame, stretcher-heads, and means for operating one of the heads, of a series of independent leather-holders adapted to engage marginal portions of the end of a body of leather at different angles thereto and having slots concealed toward their leather-engaging means, a corresponding series of inflexible coupling devices to which the holders are loosely pivoted by means of each slot to adapt them to crumple freely and adjust themselves in lateral direction under tension, and means provided on the stretcher-head and coupling devices permitting the latter to be adjusted to positions parallel with one another and for connecting them to the head, substantially as set forth.

8. In a leather-stretching machine, the combination with a stretcher-head, of a series of leather-holders having leather-engaging means on their front portions and in rear thereof slots curved in the direction of the leather-engaging means, a corresponding series of coupling devices adapted to engage in such slots and thereby pivotally connect the holders, and means for adjustably connecting the coupling-bars to the stretcher-head, substantially as set forth.

9. A leather-holder for a stretching mechanism, consisting of a body provided on its front portion with means for engaging the leather and having in rear thereof a slot concave in the direction of the leather-engaging means, a coupling-bar adapted to engage in such slot and thereby pivotally connect said body to said bar, and means for adjustably connecting the coupling-bars to the stretching mechanism, substantially as set forth.

696,717. LASTING-MACHINE. JAMES CAVARANE, Jr., Brooklyn, Mass., assignor to the United Shoe Machinery Company of the State of New Jersey, Boston, Mass. Filed Apr. 21, 1902. Serial No. 12,754. (No model.)

Claim.—1. A machine comprising grippers and means for actuating them to work on upper over a last, combined with means for superimposing wire or a similarly continuous material on said upper over-worked by said grippers to secure the upper on the last.

2. A machine comprising means for working on upper over a last, combined with means for placing wire or a similarly continuous material

in binding relation with said over-worked upper, said wire-placing means being inoperative during a portion of the operation of the machine.

3. A machine for working on upper over a last including separate means for over-working the toe portion of said upper, said means being arranged to operate upon different parts of the upper successively in repeated operations of the machine, combined with means for placing wire or a similarly continuous material in binding relation with said toe portion.

4. A lasting-machine adapted to manipulate different parts of the upper successively in repeated operations of the machine, comprising means for superimposing wire or a similarly continuous material in binding relation with said successively-manipulated parts of said upper.

5. A lasting-machine adapted for manipulating different parts of an upper successively in repeated operations of the machine, comprising means for holding wire or a similarly continuous material in left, take-up and tension device therefor, and means for superimposing said wire progressively in binding relation with said successively-manipulated parts of said upper.

6. A lasting-machine adapted to manipulate different parts of an upper successively in repeated operations of the machine, comprising means for placing wire or a similarly continuous material in position for holding said successively-manipulated parts of said upper, and means for superimposing said wire-placing operations during a number of repeated operations of said machine.

7. A lasting-machine adapted for manipulating different parts of an upper successively in repeated operations of the machine, comprising means for superimposing wire or a similarly continuous material in position for holding said successively-manipulated parts of said upper, said means being normally inoperative and put into operation as desired during the lasting process.

696,718. BALANCED SLIDE-VALVE. FRANK C. CHARLES, Cedar Rapids, Iowa. Filed Mar. 12, 1901. Serial No. 60,261. (No model.)

Claim.—1. In a balanced slide-valve, the combination of a valve having a disk attached thereto provided with two surfaces located at right angles to each other, a packing-ring fitting upon one of said surfaces and a spring-ring located upon the other of said surfaces and controlling the packing-ring to uphold the latter, and a balance-plate above the said packing-ring.

2. The improved balanced slide-valve, comprising a valve, a disk secured thereto and having a vertical face 7 and a horizontal surface 17, a packing-ring engaging the said face 7, a spring-ring carried upon the horizontal surface 17 and controlling the said packing-ring, the contacting surfaces of said two rings being relatively beveled or inclined so that the elasticity of the said spring-ring will cut through its beveled or inclined surface to hold the packing-ring firmly against the balance-plate.

696,719. SPINNING-TOY. HENRY C. COVINE, New Haven, Conn. Filed June 17, 1901. Serial No. 64,772. (No model.)

Claim.—A toy having a rounded upper end, and sides gradually tapered to a peg, a small room in the upper or rounded part of the top into which the string may be drawn as it is passed downward over the edge of which the string may be drawn as it is passed downward over the sides to the peg immediately above which the string is wound whereby the end of the string is held in engagement with the top during the winding thereof, and from which it is readily disengaged when the top is thrown, substantially as described.

696,720. METALLIC TIE AND RAIL-FITTER. BENJAMIN E. CHASE and HENRY F. CHASE, Haverford, Pa. Filed Dec. 26, 1901. Serial No. 67,126. (No model.)

Claim.—1. In a metallic tie and rail-fitter combined, the combination of an I-beam having openings formed in the upper flange thereof, pivoted clamping members secured to said tie extending through said openings when in a closed position, and means whereby the clamping members are retained in a locked position, substantially as described.

2. In a metallic tie and rail-fitter, the combination of a metallic tie formed of an I-beam, pivoted clamping members secured between the upper and lower flanges of the I-beam, said pivoted clamping members adapted to be swung outwardly, and means carried by the upper flange of the I-beam for securing the said clamping members, substantially as described.

3. In a metallic tie and rail-fitter combined, the combination of a metallic tie formed of an I-beam having openings formed therein, clamping members pivotally secured to said tie extending through said openings when in a closed position, and a yoke extending over the flange of said tie and engaging said clamping members, substantially as described and for the purpose specified.

4. In a metallic tie and rail-fitter, the combination of a metallic tie formed of an I-beam, of a pair of pivoted clamping members secured between the flanges of the I-beam on each side thereof with means carried by the upper flange of the tie for engagement with the said clamping members, whereby the latter are retained in the locked position, substantially as described.

5. In a metallic tie and rail-fitter combined, the combination of a metallic tie formed of an I-beam, of pivoted clamping members having an outward movement toward the flanges of said I-beam and adapted to engage the sides of the rail-beam, and a yoke mounted on the upper flange of the I-beam for engagement with the said clamping members whereby the latter are retained in a locked position, substantially as described.

696,721. MAIL-BOX. JOHN W. CURRIER, Boston, Mass. Filed Jan. 26, 1902. Serial No. 91,700. (No model.)

Claim.—1. A mail-box having a flat back wall and a rounded bottom, and a box-support secured to the back wall, said support being designed to receive a post or the like and being closed at top.

2. A mail-box having a flat back wall and a rounded bottom, a signal-red pivoted to the back wall, and a spring member to hold said red in set and erect position, said spring member being formed with recesses to receive and hold the red and adapted to exert a tension on the red when moving from one recess to the other.

696,722. PHYSICIAN'S EXAMINING CHAIR AND TABLE. ROBERT F. CHASE, Columbus, Ohio. Filed July 20, 1901. Serial No. 60,006. (No model.)

Claim.—1. In a physician's or surgeon's examining chair and table a base portion, levers pivoted in the forward part of the base portion, a chair back or table hinged near its middle to the upper ends of said levers, toggle-arms hinged to the lower portions of said chair back or table, and to the base portion, and a link connecting the toggle-arms and the lower ends of the said levers, substantially as described.

2. In a physician's or surgeon's examining chair and table, a base portion, a lever hinged in the base portion, a chair back or table hinged near its middle to the upper end of said lever, and means substantially as described connected with the lower end of said lever and with the lower portion of the chair-back to assist, when the upper end of the lever is

pushed downward, in elevating the lower end of the chair-back to table position.

696,723. MARINE RAILWAY. CHARLES M. DAVIS, Cambridgeport, Mass., assignor of one-half to Jonathan S. Goodrich, East Cambridge, Mass. Filed May 1, 1901. Serial No. 62,202. (No model.)

Claim.—In a marine railway, the combination with an inclined deck provided with suitable rails, of a ship-carriage arranged to travel along said rails, a plurality of gravity-pawls arranged to engage and drag along a rack during the upward travel of said carriage along said deck, connected means for simultaneously raising said gravity-pawls and maintaining them raised during the downward travel of said carriage, means for raising and lowering said carriage along said deck, a set of auxiliary spring-actuated pawls, and connections between the spring-actuated pawls and the means for actuating the carriage, arranged to permit said pawls to be thrown into engagement with the rack upon the breaking or disarrangement of the carriage-actuating means, substantially as described.

696,724. CHIMNEY AND VENTILATOR. WILLIAM DAVIS, County of Middlesex, England. Filed Sept. 22, 1901. Serial No. 70,102. (No model.)

Claim.—1. A chimney, updraft, or ventilator shaft provided in the opposite sides thereof with holes or openings, central chokes or rims secured thereto above and below said holes or openings, radial partitions between said chokes or rims and forming passages leading to said holes or openings and pivoted valves for closing said holes or openings, the diametrically opposite valves being connected, substantially as shown and described.

2. An updraft, chimney, or ventilator shaft provided with oppositely-arranged holes or openings, annular shields secured thereto above and below said holes or openings, radial partitions placed between said annular shields and forming passages leading to said holes or openings, internal pivoted valves operating to close and open said holes or openings, the oppositely-arranged valves being connected, a second series of holes or openings above the first-named holes or openings and oppositely arranged, and pivoted valves adapted to close said last-named holes or openings, the oppositely-arranged valves being connected, substantially as shown and described.

696,735. POLISHING-BRUSH. WILLIAM DEERE, New York, N. Y.
Filed July 11, 1900. Serial No. 28,178. (No model.)

Claim.—1. A polishing-brush, consisting of a block, a central bushing therein, a cylindrical middle portion of said bushing, and outwardly-flaring end portions for securing said bushing in said block, substantially as set forth.

2. The combination, with a brush-block having an opening, of a soft-metal bushing in the same and composed of a cylindrical middle portion, and portions tapering outwardly from said middle portion at each side of the same, and provided each with an outwardly-tapering opening, and end-caps projecting from said outwardly-tapering end portions into the brush-block, substantially as set forth.

3. The combination, with a brush-block having an opening, of a soft-metal bushing in the same and composed of a cylindrical middle portion, and portions tapering outwardly from said middle portion at each side of the same, and provided each with an opening tapering outwardly at a less angle than the same, and end-caps projecting from said outwardly-tapering end portions into the brush-block, substantially as set forth.

696,736. SAFETY ATTACHMENT FOR ELEVATORS. GEORGE DONNELLY, Newark, Ind.
Filed Dec. 23, 1901. Serial No. 27,282. (No model.)

Claim.—1. The combination with a reversible jaw; of a weight connected thereto and adapted to revolve said jaw and clamp or bind it upon the guide of an elevator-car, a normally tensioned spring adapted, when released, to start the weight in its rotary movement, and a lock for the weight.

2. The combination with a reversible jaw; of a weight connected thereto and adapted to revolve said jaw and clamp or bind it upon the guide of an elevator-car, means for automatically imparting rotary movement to the jaw and its weight in one direction, and means for preventing movement of said jaw in the opposite direction.

3. The combination with a reversible jaw; of a weight connected thereto and adapted to revolve said jaw and clamp or bind it upon the guide of an elevator-car, means for automatically imparting rotary movement to the jaw and its weight in one direction, a toothed disk revoluble with the jaw, and a step normally engaging the disk and adapted to prevent movement of the jaw in the opposite direction.

4. The combination with a reversible shaft; of a jaw at each end thereof, normally vertical weighted arms extending from the shaft, toothed disks upon the shaft, steps engaging the same and adapted to prevent movement in one direction, a flexible connection between said arms and a hoisting-cable, whereby the arms are retained normally vertical, and normally tensioned springs adapted, when said connections are slackened, to automatically impart a rotary motion to the arms and jaws.

5. The combination with an elevator-car and guide therefor, of standards upon said car, a revoluble shaft journaled in said standards, a jaw at each end of the shaft adapted to travel upon the guides, normally vertical weighted arms extending from the shaft, toothed disks upon the shaft, steps engaging the same and adapted to prevent movement in one direction, a flexible connection between said arms and a hoisting-cable whereby said arms are retained normally vertical, flexible connections between the car and said hoisting-cable, normally tensioned springs adapted, when said connections are slackened, to automatically impart a rotary motion to the arms and jaws, and a strip upon the arms adapted, during the rotary movement of said arms, to contact with the connections and carry them in the direction of movement of the arms.

696,737. WIRE-REELING MACHINE. WILLIAM G. DUNLAP, Portland, Me. Me.
Filed Apr. 30, 1901. Serial No. 24,167. (No model.)

Claim.—1. A machine of the class described comprising a running-gear having a frame, a shaft extending laterally from the frame and located in advance of the rear wheels and adapted to receive spools, gearing for connecting the shaft with one of the rear wheels, the bar 27 located in advance of the shaft and provided with depending approximately U-shaped guides, the bar 30 arranged at the front of the frame and extending laterally therefrom in advance of the said bar 27, the levers 28 pivoted between their ends in the bar 30 and extending above and below the same and provided at their lower ends with wire-receiving openings, the operating-lever 29 fulcrumed at its lower end and arranged between the sides of the frame, and the connecting-rod 23 connected with the operating-lever and with the upper ends of the other levers, substantially as described.

2. A machine of the class described comprising a frame, a laterally-extending shaft, a bar extending laterally from the frame, the levers 28 fulcrumed on the bar and extending above and below the same and provided at their lower ends with wire-receiving openings, the operating-lever arranged between the sides of the frame and fulcrumed at its lower end, and the rod 23 connected with the upper ends of the levers 28 and with the operating-lever, substantially as described.

696,738. STRINGER. EDWARD E. BROT, Providence, R. I.
Filed Oct. 2, 1901. Serial No. 77,493. (No model.)

Claim.—In a stringer of the class described, the combination of a tube having a helical groove; and a guard of resilient material having a bore arranged to engage the helical tube and be moved axially thereon when rotated.

696,739. RAIL-JOINT. ANDREW RUMRATH, Allegheny, Pa.
Filed Jan. 21, 1902. Serial No. 26,575. (No model.)

Claim.—1. In a rail-joint, the combination with the rails, having their ends cut away near their meeting ends, a middle straddling said rails, an integral fish-plate extending upwardly flush with the upper face of the tread of said rails, and even-ties, and means to fasten said integral fish-plate to said even-ties and rails, substantially as described.

2. In a rail-joint, the combination of the rails, having a portion of their tread cut away, a fish-plate extending to the upper face of said rails, a middle formed integral therewith forming the chair in said cut-away portions, and a downwardly-extending base formed integral with said middle, substantially as described.

696,740. COMPRESSED-AIR CONTROLLING DEVICE FOR SAND-DISCHARGER. JAMES FARLEY, Waukegan, Wis.
Filed Sept. 14, 1901. Serial No. 75,264. (No model.)

Claim.—1. The combination with an engineer's brake-valve, and its handle, of a ring clamped to said handle to move therewith, and having an inclined upper surface; an independent valve-actuating having a channel therethrough; a reciprocating spring-controlled valve intercepting said channel and having a stem projecting beyond said casing; a pipe connecting one end of said channel with the main reservoir-pipe of the brake-valve; another pipe leading from the other end of said channel; a stud projecting from said independent valve-actuating; a lever pivoted on said stud and having a bent free end resting on the inclined top surface of said ring; a disk secured to the projecting end of the reciprocating valve; an upright lever pivoted on the said stud, and having a laterally-extended curved arm for engagement with said disk; and another lever, pivoted

to the first-named lever and having a leg for engagement with the upright lever.

2. The combination with a valve-casing having a channel therethrough; of a pipe connecting one end of said channel with a compressed-air reservoir, and another pipe leading from the other end of said channel; a reciprocating spring-controlled valve in said casing, intercepting said channel and having a stem projecting beyond said casing; a disk adjustably secured to the projecting end of said valve-stem; a stud projecting from said valve-casing; a pair of levers pivoted on said stud, one extending laterally in line with said valve-casing, and the other extending upwardly and having a bent curved arm projecting beneath said valve-disk for engagement therewith, said curved arm having a step at its free end, and a series of notches in its under side, adjacent thereto; and another lever, pivoted to the first-named laterally-extending lever, and having an upwardly-projecting leg for engagement with the notches and end step of the arm of the said upright lever.

3. The combination with an engineer's brake-valve, and its handle, of a device secured to said handle to move therewith, and provided with an inclined surface; an independent valve-actuating having a channel therethrough; a valve intercepting said channel and having a stem projecting beyond said casing; pipe connections between one end of said channel and the main reservoir of the brake-valve; another pipe leading from the other end of said channel; and means connected to the said projecting valve-stem for engagement with the inclined surface of the device secured to the brake-valve handle, and whereby controlling the admission of air to and regulating its passage through said channel.

696,741. SAFETY-FAUCET AND WATER-CONTROLLING CONNECTION. RUEL G. GAMER, New York City, N. Y.
Filed Dec. 2, 1901. Serial No. 25,324. (No model.)

Claim.—1. In a safety-faucet and water-controlling connection, a faucet, connected to the water-supply house-pipe, a rod provided with a handle by means of which water can be turned into and shut off from the house-pipe, and a connection between the faucet and the rod, such connection arranged to hold the valve-plug of the faucet off from its seat; substantially as described.

2. In a safety-faucet and water-controlling connection, the combination of a faucet connected to the water-supply house-pipe, a rod whereby water may be turned into and shut off from the house-pipe, a connection between the rod and the faucet, mechanism in such connection to maintain the valve-plug of the faucet off from its seat when the rod is turned to admit water to the house-pipe and means to release such mechanism when the rod is turned to shut water off from the house-pipe; substantially as described.

3. In a safety-faucet and water-controlling apparatus a house-pipe and a faucet consisting of a casing provided with a valve-seat and a discharge-outlet, a longitudinally-movable rod in the casing, a valve-plug on the rod and a spring yieldingly holding the valve-plug on its seat, in combination with a rod movable to turn water off from and to admit water to the house-pipe and a connection between the rod and the faucet, such connection attached to the faucet to depress the longitudinally-movable rod and maintain the valve-plug off its seat; substantially as described.

4. In a safety-faucet and water-controlling connection, the combination of a faucet to the water-supply house-pipe, a rod whereby water may be turned into and shut off from the house-pipe, and a connection between such rod and the faucet such connection consisting of a pipe or tube, a cam in each pipe or tube, each cam provided with a recess and means to turn the cam, a longitudinally-movable rod in the pipe or tube and a cam on the rod controlling the admission of water to the house-pipe, the cam, longitudinally-movable rod in the pipe or tube and the plunger-rod of the faucet, so related that when the longitudinally-movable rod is in the recess of the cam in the tube or pipe the faucet is open and the rod controlling the admission of water to the house-pipe may be turned to admit water into the house-pipe or to shut water off from the house-pipe, as desired, and when such longitudinally-movable rod is in front of

the cam on the rod controlling the admission of water to the house-pipe it is out of the room in the cam and such rod controlling the admission of water to the house-pipe is in position to permit the water in the house-pipe to run to waste and such rod cannot be turned to admit water in the house-pipe, and at such time the cam in the pipe or tube can be turned in open or close the valve of the faucet, as desired; substantially as described.

696,782. DIFFERENTIAL LETTER-SPACE REGISTER FOR COMPOSING-MACHINES. GEORGE A. GOSMAN, Minneapolis, Minn., assignor to the Goodson Graphotype Company, New York, N. Y., a Corporation of New Jersey. Filed Sept. 3, 1901. Serial No. 74,062. (No model.)

Claim.—1. A register for composing-machines, which register has, in combination, a primary unit-counter, a secondary unit-counter, or justification-indicator, and an adjustable driving device, for operating the secondary counter from the primary counter, whereby the primary counter may be made to begin to move the secondary counter at any desired step of the primary counter's movement, thus adapting the register for lines of different length, substantially as described.

2. A register for composing-machines, which register has, in combination, a primary unit-counter, a secondary unit-counter or a justification-indicator, and a driving device for operating the secondary counter from the primary counter, which driving device has a twofold or double adjustment, to wit, one adjustment in units, within a limited range, and another adjustment in multiples of the range limit of said unit adjustment, substantially as and for the purposes set forth.

3. In a composing-machine, having a traveling element under the control of the operator at the keyboard, of a differential letter-space register, and releasing connections for permitting the counting devices of said register to return to their normal or initial starting positions, which releasing connections are operated automatically from said traveling element of the composing-machine, substantially as and for the purposes set forth.

4. In a letter-space register, the combination with the counting devices, of a friction-brake operative on some movable element of the counting device, to check the return motion and prevent any backlash of said counting device, substantially as described.

5. In a letter-space register, the combination with counting devices subject to springs for returning the same to their normal or initial starting positions, of ratchet and pawl devices for moving said counting devices against the tension of said springs, in the counting action, and an automatic friction-brake operative on some movable member of said counting devices for checking the return motion and preventing backlash of said counting devices, substantially as described.

6. In a letter-space register, the combination with counting devices

subject to springs for returning the same to their normal or initial starting positions, of ratchet and pawl devices for moving the counting devices against the tension of said springs, in the counting action, a friction-brake for action on said counting device during the return motion thereof only, and a releasing device operative to release the pawls from the ratchet and to set the brake, substantially as described.

7. In a letter-space register, the combination with the primary counter having the main gear-wheel *B*, of the secondary counter having the gear-wheel *C* and the intermediate driving device, for operating the secondary from the primary counter, comprising a driving-arm pivoted to the arbor of the primary counter and adapted to be locked in different adjustments to said gear-wheel *B*, the radius-bar *D* pivoted to the arbor of the primary counter and having the secondary gear *E* in mesh with the gear-wheel *C* of the secondary counter and the spring-arm *F* also pivoted to the arbor of the primary counter and adapted to be locked to said segment *C*, in different adjustments, all for co-operation, substantially as described.

696,783. MATRIX FOR TYPE-FOUNDING. GEORGE A. GOSMAN, Minneapolis, Minn., assignor to the Goodson Graphotype Company, New York, N. Y., a Corporation of New Jersey. Filed Sept. 3, 1901. Serial No. 74,062. (No model.)

Claim.—1. An integral-plate matrix-block having the entire casting-surfaces of all of its matrices composed of comparatively soft metal, such as copper, and surrounded by a body of comparatively hard metal, such as nickel, exposed on the face of the matrix-block, so as to afford the bearing-surfaces on the face of the block, substantially as described.

2. An integral-plate matrix-block composed of an integral-plate matrix-shell of copper, electroplated from a form of type, and a body of nickel, electroplated, on the back of said shell of copper, which block, so formed, has the copper plated off from the high surfaces of its face to expose the nickel as the bearing-surfaces on the face of the block, substantially as described.

3. The process of forming a matrix having its casting surface of copper and its bearing-surfaces of nickel, which consists in first depositing a shell of copper, under the electroplating process, on a form of type, then depositing a body of nickel, under the electroplating process, on the shell of copper, and finally, plating off the copper from the face of the matrix-block so as to expose the nickel as the high or bearing surfaces of the matrix-block, substantially as described.

696,784. FONT OF TYPE. GEORGE A. GOSMAN, Minneapolis, Minn., assignor to the Goodson Graphotype Company, New York, N. Y., a Corporation of New Jersey. Filed Sept. 3, 1901. Serial No. 74,064. (No model.)

Claim.—A font of type containing kernal type with untrimmed kerns and other co-operating type with casting-surfaces for receiving or seating the kerns of said kernal type when the type are set, which casting-surfaces are formed partly on the type proper and partly on the type-body, substantially as and for the purposes set forth.

696,785. GAME APPARATUS. LOUIS C. HENNINGER, Belleville, Ill. Filed Mar. 16, 1900. Serial No. 8,616. (No model.)

Claim.—A game apparatus comprising a rotatable standard, a wheel rotatably mounted in front of the same, a series of rigid concentric circular dial-plates forming said wheel and revolving together as a unit, said plates being separated a suitable distance apart and in a step-like form, a spindle passing through the series of dial-plates, numbers arranged upon

the outer surfaces of said concentric plates and running in consecutive order from the outer to the inner plate, a closed horizontal extension forming a part of said standard and projecting therefrom over the edges of the dial-plates, spring-plates of variable lengths disposed in the same plane and having their upper or fixed ends secured to said forked extension, and pins projecting from said dial-plates at right angles to the spring-plates and located between the numbers, and co-operating with the free ends of the spring-plates, substantially as set forth.

696,786. FILLING-NOZZLE FOR FLUID-HOLDING TANKS. FRANK W. HOWARD, Brooklyn, N. Y., assignor to Knapton Steamboat-borough, Brooklyn, N. Y. Filed May 31, 1901. Serial No. 62,546. (No model.)

Claim.—1. A filling-nozzle for fluid-holding tanks, comprising an open-ended valve-case having a flaring mouth, a reduced cylindrical neck with a valve-seat at the end thereof and an enlarged threaded end portion with openings therein, a valve having an integral X-stem which fits the said reduced neck, a cap fitting upon and covering the enlarged portion of the valve-case, and a spring between the said valve and cap, substantially as specified.

2. A filling-nozzle for fluid-holding tanks, comprising an open-ended valve-case having a flaring mouth, a reduced cylindrical neck with a valve-seat at the end thereof and an enlarged threaded end portion with openings therein, a valve fitting said neck and having upon one side an integral X-stem movable longitudinally in said reduced neck and an integral cap-seat on the other side, a cap fitting upon and covering the enlarged threaded end of the valve-case and having a central integral cap-seat oppositely placed to the cap-seat of the valve, and a spring having its respective ends in the said cap-seat, substantially as specified.

696,787. CONDUIT FOR UNDERGROUND CONDUCTORS. FRANK JAMES, Liverpool, England. Filed Sept. 4, 1901. Serial No. 74,066. (No model.)

Claim.—1. A system of underground conductors for the distribution of electrical energy for lighting or power, comprising a strong construction of conductors, conductors consisting of naked wires or rods within said conductors, and a filling of insulation within the conductors and about the conductors, said filling being of material having highly-insulating properties suited to currents of this nature and adapted to set more or less hard without becoming brittle, substantially as hereinafter set forth.

2. A system of underground conductors for the distribution of electrical energy for lighting or power, comprising a strong construction of conductors, conductors consisting of naked wires or rods within said conductors, supports of highly-insulating material adapted to retain the conductors in position, and a filling of insulation within the conductors and about the conductors, said filling being of material having highly-insulating properties suited to currents of this nature and adapted to set more or less hard without becoming brittle, substantially as hereinafter set forth.

3. In a system of underground conductors for the distribution of electrical energy for lighting or power, the combination with the conductors and the conductors therein, of a conduit-filling of highly-insulating material adapted to set more or less hard without becoming brittle and which is thoroughly neutral or free from all mineral acids and alkaline and aqueous matters substantially as described.

4. In a system of underground conductors for the distribution of electrical energy for lighting or power, the combination with the conductors and the conductors therein, of a conduit-filling of coal-tar pitch and refining materials, said filling being thoroughly neutral or free from all mineral acids and alkaline and aqueous matters, substantially as described.

5. In a system of underground conductors for the distribution of electrical energy for lighting or power, the combination with the conductors, of a non-brittle filling of coal-tar pitch and creosote-oil therein, said filling being thoroughly neutral or free from all mineral acids and alkaline and aqueous matters, and conductors within said conductors consisting of naked wires or rods bedded in the filling, substantially as described.

6. In a system of underground conductors for the distribution of electrical energy for lighting or power, the combination with the conductors and the conductors, of conductor-supports consisting of loose strips of insulating material inclined and arranged crosswise in the conductors, substantially as described.

7. In a system of underground conductors for the distribution of electrical energy for lighting or power, the combination with the conductors and the conductors, of loose strips of insulating material arranged crosswise in the conductors to form conductor-supports and means for supporting said strips in that position, substantially as described.

8. In a system of underground conductors for the distribution of electrical energy for lighting or power, the combination with the conductors and the conductors, of loose strips of insulating material inclined and arranged crosswise in the conductors to form supporting-cliffs for a plurality of conductors and adapted to prevent said conductors from coming in contact with the conductors and with each other, and means for supporting said strips in that position, substantially as described.

9. In a system of underground conductors for the distribution of electrical energy for lighting or power, the combination with the conductors and the conductors, of strips of insulating material inclined and arranged crosswise in the conductors to form independent supporting-cliffs for a plurality of conductors, the inner lower face of the conductors having a central groove and supports in said groove for the adjacent ends of said strips, substantially as described.

10. In a system of underground conductors for the distribution of electrical energy for lighting or power, the combination of a series of conductors having longitudinal grooves adapted to meet at the joints, of metallic dovetail or key pieces located in said grooves to lap the joints, and a filling of cement in the grooves adapted to bind the several parts, substantially as described.

11. In a system of underground conductors for the distribution of electrical energy for lighting or power the conductors having lateral grooves running longitudinally in a continuous manner, and adapted to contain dovetail or key-pieces to lap the joints with a filling to bind them therein, and insulating-supports for the conductors in the conductors, substantially as described.

12. In a system of underground conductors for the distribution of electrical energy, for lighting or power, the combination with the conductors and an insulating-filling therein about the conductors, of wood covers bedded into the filling below the top of the conductors, and a layer of cement on said covers in a space up to the top of the conductors, substantially as described.

13. In a system of underground conductors for the distribution of electrical energy, for lighting or power, the combination with the conductors and its insulating-filling therein about the conductors, of wood covers bedded into the filling below the top of the conductors, a layer of cement on said covers in a space up to the top of the conductors, and a solid cover over all, substantially as described.

14. A system of underground conductors for the distribution of electrical energy for lighting or power, comprising conductors A having multiple ducts conductors B insulatingly supported in said ducts, and surrounded with insulation therein, longitudinal groove B, between the ducts and metallic rod M embedded in a filling in said groove adapted to lap the conductors for the purpose of imparting strength thereto and of carrying the return-current, substantially as described.

15. In a system of underground conductors for the distribution of electrical energy, for lighting or power, the combination of conductors A, groove B, support U held in said groove, and inclined strips J of highly-insulating material, coating with the support U to support three conductors B within the conductors out of direct contact with the support U and conductors, substantially as described.

696,788. APPARATUS FOR REFINING AND DELIVERING GLASS. WASHINGTON B. EYRE, Kalamazoo, Pa. Filed Aug. 27, 1900. Serial No. 28,127. (No model.)

Claim.—1. A glass-furnace having a refining-compartment the end wall of which is formed with a cast, and a superheating-compartment mounted to turn on a horizontal axis in said cast and normally in commu-

ization with the refining-compartment and forming a continuation thereof, the superrefining-compartment being adapted to be turned to break said communication and discharge its contents, substantially as shown and described.

1. A glass-furnace having a refining-compartment the end wall of which is formed with a seat, and a superrefining-compartment mounted to turn on a horizontal axis in said seat and normally in communication with the refining-compartment and forming a continuation thereof, the rear wall of the superrefining-compartment serving, when the same is oscillated, to sever the glass therein from that contained in the refining-compartment and to close the latter and to discharge its own contents directly for working substantially as shown and described.

2. A glass-furnace having a refining-compartment the end wall of which is formed with a seat, and a superrefining-compartment mounted to turn on a horizontal axis in said seat and normally in communication therewith and forming a continuation thereof, the front wall of the movable compartment being higher than the rear wall and adapted normally to close against the roof of said seat and exclude the outer air, the movable compartment when oscillated being adapted to close the refining-compartment and discharge its own contents, substantially as shown and described.

696,789. ORS-CLASSIFIER. JOHN KLEIN, Des Moines, Mo. assignor of two-thirds to Paul A. Fox and Charles D. McLaughlin, St. Louis, Mo. Filed July 12, 1901. Serial No. 64,044. (No model.)

Claim.—1. An ore-classifier, consisting of a hopper adapted to receive the mixture containing the ore, an ore-outlet, a charge-outlet, an agitator within the hopper, gearing for operating the agitator, and a device for automatically stopping the agitator when the hopper contains too much ore, substantially as specified.

2. An ore-classifier, consisting of a hopper adapted to receive the mixture containing the ore and having an ore-outlet and a charge-outlet, a water-pipe leading into the hopper and directed toward the ore-outlet, an agitator within the hopper, gearing for operating the agitator, and a device for automatically stopping the agitator when the hopper is receiving more ore than can be discharged through the ore-outlet, substantially as specified.

3. An ore-classifier, consisting of a hopper having an ore-outlet near its lower end, and a charge-outlet at its upper end, a water-pipe leading into the hopper and directed toward the ore-outlet, an air-pipe leading into the hopper transversely of the water-pipe and directed toward the charge-outlet, an agitator within the hopper, means for operating the same, and means for automatically disconnecting the agitator from the operating means when too much ore is contained in the hopper, substantially as specified.

4. An ore-classifier, consisting of a hopper adapted to receive the mixture containing the ore and having an ore-outlet near its bottom and a charge-outlet at its top, a water-pipe leading into the hopper and directed toward the ore-outlet, an air-pipe leading into the hopper below the ore-outlet, transversely of the water-pipe and directed toward the charge-outlet, an adjustable agitator within the hopper, a driver for operating the agitator, and means for automatically disconnecting the agitator from the driver when more ore is contained within the hopper than can be discharged through the ore-outlet, substantially as specified.

696,740. LASTING-MACHINE. SHERMAN W. LAMB, NEWBY, Mass. assignor to the United Shoe Machinery Company of the State of New Jersey, Boston, Mass. Filed Apr. 19, 1901. Serial No. 13,462. (No model.)

Claim.—1. A machine for working an upper over a last, comprising mechanism for processing individual fastenings, mechanism for supplying continuous fastening material, and means for rendering either of said mechanisms operative or inoperative.

2. A machine for working an upper over a last, comprising a plurality of mechanisms for supplying different kinds of fastening material, and means for rendering either of said mechanisms operative during a single operation of the over-working mechanism.

3. In a machine for working an upper over a last, mechanism for securing the over-worked upper in position, means to suspend the operation of said mechanism and a second mechanism adapted to operate for supplying fastening material while said first mechanism is inoperative.

4. In a machine for working an upper over a last, means to pluck or crimp the upper, mechanism for supplying wire-fastening material, and means to render said mechanism operative when said plucking means is operative.

5. In a machine for working an upper over a last, pinners for gripping the upper, means to turn the pinners, wire-placing mechanism and means to render said mechanism operative when the pinners are turned.

6. In a machine for working an upper over a last, pinners for gripping the upper, means to turn the pinners to either side, wire-placing mechanism and means to render said mechanism operative when the pinners are turned to one side, said mechanism being inoperative when the pinners are turned to the other side.

7. In a machine for working an upper over a last, pinners for gripping the upper, means to move the pinners to either side, wire-placing mechanism and means to render said mechanism operative when the pinners are moved to one side, said mechanism being inoperative when the pinners are moved to the other side.

8. A machine for working an upper over a last comprising means for inserting fastenings, means to suspend the insertion of said fastenings during a number of repeated operations of said machine and means for placing wire or a similarly continuous material in position for holding the parts of said upper which are manipulated by operation of said machine taking place during said suspension of the insertion of said fastenings.

9. In a machine of the class described, means for working an upper over a last, auxiliary upper-manipulating mechanism normally occupying an inoperative position, means for placing wire or a similarly continuous material in position for holding said upper, said means normally occupying an inoperative position, means to advance said auxiliary mechanism

as desired for use and means to put simultaneously said wire-placing means into operative position.

10. In a machine of the class described, means for working an upper over a last, auxiliary upper-manipulating mechanism normally occupying an inoperative position, means for placing wire or a similarly continuous material in position for holding said upper against displacement, said means normally occupying an inoperative position, mechanism for putting said auxiliary mechanism in operative position and simultaneously putting said wire-placing mechanism in operative position and means for rendering said mechanism inoperative relatively to the wire-placing mechanism at times.

11. In a machine of the class described, grippers, mechanism for actuating them to work an upper over a last, means for superimposing wire or a similarly continuous material in position for holding said over-worked upper, and means controllable by the workman for varying the tension of said wire during the operation of said machine.

12. In a machine for working an upper over a last, mechanism for delivering different-sized tasks, a device to change the size of tasks delivered by said mechanism and independent means controlling the size-changing operation of said device to prevent the delivery of any task.

13. In a machine for working an upper over a last, two task-passways for different-sized tasks, a device to receive tasks therefrom, means to change the relative positions of said passways and said device and thereby change the size of tasks delivered to said device and independent mechanism to change the relative positions of said passways and said device and thereby prevent the delivery of tasks.

696,741. MOTOR-CAR. JOHN C. HARTMAN, Three Rivers, Mich. assignor to the Sheffield Car Company, Three Rivers, Mich. Filed Sept. 7, 1900. Serial No. 39,945. (No model.)

Claim.—1. In a motor-car the combination of the framework; suitable bars or plates H under the framework and secured thereto, provided with seats for the housing of the driving-gear and with holes for the supporting-rod for the cylinder; axles B, B, with driving-wheels B', B', B'', B'', secured thereto; cranks or wrist-pins on said driving-wheels in the same relative positions at each side, but arranged at an angle to each other on opposite sides; parallel coupling-rods E, E, coupling the wheels at each side together by means of said cranks and wrist-pins; an engine-cylinder to each side of said frame supported on the rods C' extending transversely across the frame through the holes in the plate H, said cylinder being open from end to end; piston-heads D', D', in the ends of said cylinder adapted to reciprocate to and from the center thereof; pinions D extending out at opposite ends of said cylinder and connecting said pinions to oppositely-arranged wrist-pins or cranks on the driving-wheel all coacting for the purpose specified.

2. In a motor-car the combination of the framework; suitable bars or plates H under the framework and secured thereto, provided with seats for the housing of the driving-gear and with holes for the supporting-rod

for the cylinder; axles B, B, with driving-wheels B', B', B'', B'', secured thereto; cranks or wrist-pins on said driving-wheels in the same relative positions at each side, but arranged at an angle to each other on opposite sides; parallel coupling-rods E, E, coupling the wheels at each side together by means of said cranks and wrist-pins; an engine-cylinder supported on the rods C' extending transversely across the frame through the holes in the plate H, said cylinder being open from end to end; piston-heads D', D', in the ends of said cylinder adapted to reciprocate to and from the center thereof; pinions D extending out at opposite ends of said cylinder and connecting said pinions to oppositely-arranged wrist-pins or cranks on the driving-wheel all coacting for the purpose specified.

3. In a motor-car the combination of the framework; axles B, B, with driving-wheels B', B', B'', B'', secured thereto; cranks or wrist-pins on said driving-wheels in the same relative positions at each side, but arranged at an angle to each other on opposite sides; parallel coupling-rods E, E coupling the wheels at each side together by means of said cranks and wrist-pins; an engine-cylinder open from end to end; piston-heads D', D', in the ends of said cylinder adapted to reciprocate to and from the center thereof; pinions D extending out at opposite ends of said cylinder and connecting said pinions to oppositely-arranged wrist-pins or cranks all coacting for the purpose specified.

4. In a motor-car, the combination of the framework; axles B, B, with driving-wheels B', B', B'', B'', secured thereto; coupling means for said axles and driving-wheels; an engine-cylinder open from end to end; piston-heads D', D', in the ends of said cylinder adapted to reciprocate to and from the center thereof; pinions D extending out at opposite ends of said cylinder and connecting said pinions to oppositely-arranged wrist-pins or cranks, all coacting for the purpose specified.

5. In a motor-car the combination of the framework; driving-wheels secured to suitable axles thereunder; parallel coupling-rods coupling said driving-wheels and axles together, said coupling-rods being connected in different relative positions to said wheels; an engine-cylinder open at both ends; pistons toward each end of said engine-cylinder and adapted to reciprocate to and from the center thereof; and couplings from said pistons to the driving-wheels arranged to drive the front and rear wheels in the same direction on the outward stroke of the pistons, coacting for the purpose specified.

6. In a motor-car, the combination of the framework; driving-wheels secured to suitable axles thereunder; coupling means between said axles and driving-wheels; an engine-cylinder open at both ends; pistons toward each end of said engine-cylinder and adapted to reciprocate to and from the center thereof; and couplings from said pistons to the driving-wheels arranged to drive the front and rear wheels in the same direction on the outward stroke of the pistons, coacting for the purpose specified.

7. In a motor-car, the combination of the framework; bars of metal beneath the same; bearings secured to said bars carrying the axles and driving mechanism; and an engine-cylinder suspended from said bars with oppositely-acting pistons therein coupled to said driving-gear, said pistons to act simultaneously in opposite directions, whereby twisting of the frame is avoided, as specified.

696,742. ONE-OPERATED VENDING-MACHINE. GEORGE I. MERRILL and GEORGE TILLOTSON, Shelby, England. Filed Dec. 7, 1900. Serial No. 39,915. (No model.)

Claim.—1. A machine of the class described provided with a tilting device 21, a coin-holder and plate pivoted in the top thereof and provided with pivot-jaws 27, said parts being adapted to operate as a fraud-preventive, substantially as shown and described.

2. In a machine of the class described, a pivoted coin-holder 28, a plate 26, pivoted at the top thereof and provided with pivoted jaws 27, a tilting device 21 pivotally connected with said holder, another tilting device 40 pivotally connected with the lower portion of said holder and provided with fingers or projections 50, a lever 54 pivotally supported at one side of said holder and adapted to operate the tilting device 21, the said holder being also provided at its upper end with a hookwork and upwardly directed extension 53, substantially as shown and described.

3. In a machine of the class described, a pivoted coin-holder, a plate pivoted to the top thereof and provided with pivoted jaws 27, a tilting

device pivotally connected with said holder, a second tilting device pivotally connected with the lower portion of said holder and provided with projecting fingers, a lever pivotally supported at one side of said holder and operating in connection with the last-named tilting device, said holder being also provided with a backwardly and forwardly directed extension, substantially as shown and described.

696,743. COTTON-BALING MACHINE. BRADLEY MOSE, JEFFERSON, N. C. Filed Nov. 4, 1901. Serial No. 81,308. (No model.)

Claim.—1. In an apparatus for baling cotton, the combination of a flat-frame having a hollow journal, and having one of its sides hinged, a separable reel having one of its parts journaled in the main part of the flat-frame and its other part journaled in the hinged side, and means for holding the parts of the reel together, and a tension device within the flat-frame; substantially as described.

2. In an apparatus for baling cotton, the combination of a flat-frame, a reel journaled in the flat-frame, and provided with a toothed wheel, a lever pivoted on the flat-frame and carrying a pawl arranged to engage the toothed wheel and adjustable means for causing the movement of the lever on its pivot as the flat-frame rotates; substantially as described.

3. In an apparatus for baling cotton, the combination of a flat-frame, having one of its sides hinged, a reel comprising two parts, each consisting of a reel-head and a portion of the shaft, one of said parts being journaled in the main portion of the flat-frame, and the other journaled in the hinged side, and means for securing the parts of the reel together; substantially as described.

4. In an apparatus for baling cotton, the combination of a flat-frame having one of its sides hinged, a reel comprising two parts, each consisting of a reel-head and a portion of the shaft, one of said parts being journaled in the main portion of the flat-frame and provided with means for rotating it, and the other journaled in the hinged side, and means for securing the parts of the reel together; substantially as described.

5. In an apparatus for baling cotton, the combination of a flat-frame, having one of its sides hinged, a reel comprising two parts, each consisting of a reel-head and a portion of the shaft, one of said parts being journaled in the main portion of the flat-frame and provided with means for rotating it, comprising a toothed wheel, a lever carrying a pawl and pivoted on the main portion of the flat-frame, and adjustable means for moving the lever, and the other journaled in the hinged side, and means for securing the parts of the reel together; substantially as described.

696,744. WINDOW-SCREEN. CHARLES J. GUNNERTON and JAMES F. ABRAMSON, St. Louis, Mo. Filed May 13, 1901. Serial No. 80,989. (No model.)

Claim.—In combination with a window-frame provided with parallel guide-strips, of a screen comprising a frame, having its two outer sides provided with flanges or right-angled projections adapted to fit upon one side of the parallel strips, a series of stationary metal guide plates or pieces connected to one of the sides so as to fit upon the opposite side of one of the parallel strips and a series of vertical strips secured to the outer

face of the other side of the frame and provided with two rivets or pins, and a sliding strip provided with the angular or flanged outer end, the right-angled inner end and the intermediate depressed portion provided with the parallel slots in which fit the rivets or pins of the plate so that the flanged outer end of the sliding strip may be caused to fit upon the opposite side of the parallel strip.

696,745. PUNCH-DRUCK. EDWIN O'BRIEN, Chicago, Ill. Filed May 18, 1901. Serial No. 80,514. (No model.)

Claim.—A holding-druck comprising a split compressible sleeve having a cylindrical interior and conical exterior, and provided at intervals around its periphery with longitudinally-extending, radially-disposed cuts or slots extending the full length of said sleeve, and whereby the latter is rendered capable of compression to grip a cylindrical body inserted therein, a ram arranged to abut against the upper end of said sleeve, and externally threaded at its lower end, a clamping-screw threaded upon the lower end of said ram and provided with a conical interior adapted to co-operate with the exterior of the holding-druck, the end of the ram being adapted to rest directly against the end of a punch having a conical-point consistent with its longitudinal axis, and a recess formed in the end of said ram adapted to receive such conical-point, substantially as described, and for the purpose set forth.

696,746. VEHICLE-TIRE. CHARLES A. PETER, Brooklyn, N. Y. Filed July 2, 1901. Serial No. 80,971. (No model.)

Claim.—1. The combination in a tire of a driver base portion, a solid core or buffer disc, and a cushion; together with a cover, binding-wires embedded therein, and internal flanges, said flanges and the solid core embracing the cover edges about the binding-wires.

2. In a vehicle-tire, in combination, a fully, a metal tire therefor, a solid core composed of a series of slatted sections, a flexible binding-strip for said sections, a cushion arranged about said core, a cover, binding-wires circumferentially disposed near the free edges of said cover, and fabric reinforcement therefor; together with internal flanges embracing the cover and means for holding said flanges in place.

3. In a vehicle-tire, in combination, a fully, a metal tire enclosing same, a conical solid core portion about said metal tire, a cover, retaining wires or strands therefor, alternate layers of rubber and fabric arranged in said cover, and extending about the retaining wires or strands, internal flanges for the tire, and means for holding the flanges in position.

696,747. OIL-SAVER. CLARK F. RUBY, Washington, W. Va. Filed Mar. 14, 1901. Serial No. 81,511. (No model.)

Claim.—1. The combination of a vertically-divided casing-closure formed with a vertical passage contracted below its upper end to form a packing-obstruction, and a vertically-divided packing-compressing device vertically adjustable in the upper portion of the casing-passages, said device being formed with a camber, substantially as shown and described.

2. The combination of a vertically-divided casing-closure having a central cable-passing, said passage being contracted at its lower end and threaded at its upper end, compressible material surrounding the cable immediately above the contracted lower portion of said cable-passing, and a vertically-divided screw operative in the threaded upper end of the passage for compressing said material and expanding it laterally, substantially as shown and described.

3. The combination of a casing-head, the vertically-divided casing-cap having a cable-passing, said passage being threaded at its upper end, a vertically-divided bushing in the lower end of the passage, compressible material surrounding the cable and resting on the bushing, and the vertically-divided and vertically-operated screw operative in the threaded upper portion of the cable-passing for compressing said material and causing it to expand laterally, substantially as shown and described.

696,748. ROPE-CLAMP. CLARK F. RUBY, New Martinsville, W. Va. Filed May 20, 1901. Serial No. 81,114. (No model.)

Claim.—1. The combination of a clamp-head formed with a vertical cable-inserting passage leading to its downwardly-tapering bore, downwardly-tapering cable-securing mechanism operative within the tapering bore, and means operative within the cable-inserting passage for raising the cable-securing mechanism, substantially as shown and described.

2. A clamp for well-drilling cables comprising a head having a vertical bore and a lateral slot leading to the bore, vertically-movable cable-clamping mechanism operative within the head-bore, a device operative through the head-slot for moving vertically said clamping mechanism, and means for operatively mounting said device on the said head, substantially as shown and described.

3. The combination of a clamp-head having a downwardly-tapering bore and formed with a vertical cable-inserting passage, downwardly-tapering cable-securing mechanism operative within the tapering bore, and a lifting device removably positioned within the cable-inserting passage and formed to interlock with the cable-securing mechanism, substantially as shown and described.

4. The combination of a clamp-head, cable-securing clips operative therein, one of said clips being formed with a wrench-head, and a lever-wrench adapted to be fit around to the head and operatively engage said clip for loosening it, substantially as shown and described.

5. The combination of a clamp-head formed with a cable-inserting passage, cable-securing clips operative within the head, one of said clips overhanging said passage and inclined to form a rest, the opposite face of the cable-passing being formed with bearing-points, and a lever-wrench adapted to bear therein and operatively engage the rest-clip, substantially as shown and described.

6. The combination of a clamp-head formed with a cable-inserting passage, cable-securing clips operative within the head, one of said clips overhanging said passage, and means operative in said passage for loosening said overhanging clip, substantially as shown and described.

696,749. GUIDE FOR OIL-Well-PUMP RODS. CLARK F. RUBY, New Martinsville, W. Va. Filed Sept. 11, 1901. Serial No. 78,086. (No model.)

Claim.—1. Means for holding deep-well pumps from rotating comprising a body having a vertical passage-way, said passage-way being of such form as to prevent rotation of the pump-rod which reciprocates therethrough, and tube-impinging springs projecting laterally from said body, said springs being of sufficient strength to resist rotation of the pump-rotating mechanism and pump.

2. Means for holding deep-well pumps from rotating comprising a body having a vertical passage-way, said passage-way being of such form as to prevent rotation of the pump-rod which reciprocates therethrough, and elongated outwardly-bowed springs secured at their ends to the body, said springs being adapted to lap the well-tube and resist rotation of the pump-rotating mechanism and pump.

3. Means for holding deep-well pumps from rotating in the well-tubing comprising a device adapted to frictionally engage the interior surface of the tube, said device having a vertical passage-way of such form as to prevent rotation thereof of the pump-rod which reciprocates therethrough, and means for varying the frictional engagement of said device with the tube.

4. In a device of the character described, the combination of a deep-well-pump-rotating rod angular in cross-section, an elongated body having an angular passage through which the rod reciprocates, said body being threaded at one end, elongated outwardly-bowed tube-impinging springs secured at one end to the body, a non-rotatable head slidable over the

threaded portion of the body and to which the opposite ends of the springs are secured, and a nut adjustable on the body for securing the said head, substantially as shown and described.

5. In a device of the character described, the combination of a pump-actuating rod angular in cross-section, a body having an angular passage through which the rod reciprocates, a resilient tube-impinging device carried by the body and adapted to be projected laterally by being contracted, and means for contracting said device, substantially as shown and described.

6. The combination of a rod adapted to be interposed between a deep-well pump and its actuating means, an elongated non-rotatable body through which the rod is adapted to reciprocate, outwardly-bowed leaf-springs secured at one end to the body, and a head vertically adjustable on the body to which the opposite ends of the springs are secured.

696,750. DEVICE FOR MOUNTING ENTOMOLOGICAL SPECIMENS. CLARENCE B. RYER, Maplewood, N. J. Filed Feb. 10, 1900. Serial No. 8,551. (No model.)

Claim.—1. In a device for mounting entomological and other natural-history specimens and the like, the combination of a box, a filling of batting therein in which the specimen forms the depression for or holds itself, a transparent cover-plate, and means for securing said plate and box together, substantially as described.

2. A mounting for entomological and other natural-history specimens or the like, consisting of a box, a filling of batting therein on which the specimen is placed, and in which the specimen forms the depression for or holds itself, a transparent cover-plate resting on said batting and the specimen, and means for securing said plate and box together, whereby the specimen is pressed against the cover-plate by the batting and is electrically supported from behind at substantially all points, substantially as described.

3. In a sealed mount for entomological, natural-history, or botanical specimens, the combination with a backing or tablet having an upper surface adapted to receive and support a specimen; of an inclosing and protecting frame or boxing for said backing comprising an upper section having a transparent top; a lower section upon which said backing rests; and a covering and binding strip secured to said upper section and having depending flaps adapted to hold said lower section and its superposed backing in place.

4. In a sealed mount for entomological, natural-history or botanical specimens; the combination with a backing or tablet having an upper surface adapted to receive and support a specimen; of an inclosing and protecting frame or boxing for said backing comprising an upper section; a transparent top; a lower section upon which said backing rests; and a covering and binding strip pasted to said upper section and having flaps by means of which said transparent top is secured in place; and depending flaps on said strip adapted to hold said lower section and its superposed backing in place.

5. A sealed mount for entomological, natural-history, or botanical specimens, comprising a backing or tablet of yielding material adapted to receive and support a specimen on its surface; a boxing or frame inclosing and protecting said backing; and a transparent plate secured to said backing, and between which and said yielding backing the specimen is held.

6. A sealed mount for entomological, natural-history, or botanical specimens comprising a backing or tablet of yielding fibrous material adapted to receive and support a specimen on its surface; a boxing or frame inclosing and protecting said backing; a transparent plate secured in said backing, and between which and said yielding backing the specimen is held; and a covering-strip secured to and surrounding said backing.

7. In a mount for entomological, natural-history, or botanical specimens; the combination with a backing or tablet formed of fibrous material, of an inclosing and protecting boxing or frame for said backing, comprising an upper section having a transparent top, and a lower section in which said backing rests, fitted to said upper section.

696,751. BLUE SULFUR DYE AND PROCESS OF MAKING SAME. GUNTERMAN, Ed. Bado, Switzerland, assignor to Aniline Colour and Extract Works, formerly John B. Gaily, Bado, Switzerland, a Corporation. Filed Aug. 28, 1901. Serial No. 78,642. (No specimens.)

Claim.—1. The process of making a new blue color dyestuff by reacting on dimethyl-para-amido-phenyl-guanoimid, viz., the isophthal from dimethyl-para-aminophenylguanidine and carbonic acid, of the following formula:

with a normal sulfite to form a new sulfite-acid of dimethyl-para-amido-para-aminophenylguanidine, and then treating the same with polysulfide of alkali, substantially as described.

2. As a new article of manufacture the blue color dyestuff derived from dimethyl-para-amido-para-aminophenylguanidine sulfite-acid, which forms a blue paste or in dry state a blue powder with metallic aspect, almost insoluble in water and in carbonate of sodium, easily soluble in a hot solution of caustic soda with a pale-blue coloration, scarcely soluble in alcohol, insoluble in ether and benzene, soluble in concentrated sulfuric acid with blackish-blue color, insoluble in diluted mineral acids, easily soluble in sodium sulfite to a pale-blue solution, turning by an excess of sodium sulfite to a clear grayish-violet solution, growing pure blue by the oxygen of the air, and dyeing concentrated cotton in a bath containing sodium sulfite and salt pure-blue shades of great fastness, substantially as described.

696,752. MEANS FOR AUTOMATICALLY CONTROLLING CAR MOTORS AND BRAKES. JOHN H. ROBERTSON, New York, N. Y. Filed July 20, 1898. Serial No. 726,022. (No model.)

Claim.—1. In a power-propelled vehicle having a power-actuated brake, a weight-controlled means for automatically shutting off the motive power and applying the brake when the weight is removed, the said weight-controlled means being mechanically independent of the power-actuated brake.

2. In an electrically-propelled vehicle having an air-brake, a weight-controlled means for automatically shutting off the motive current and feeding compressed air to the brake when the weight is removed, substantially as set forth.

3. In an electrically-propelled car having an air-brake, a current-out-off device, a brake-controller, air-pipes and an auxiliary platform arranged, when weight is applied therein, to close the admission of air to the current-out-off device and open it through the brake-controller, and when the weight is removed, to close the admission of air to the brake-controller, open it to the current-out-off device and also to the brake, substantially as set forth.

4. A controlling mechanism for street-railway cars comprising a current-out-off device, a brake-controller, air-pipes leading through the controller to the brake, an air-pipe leading from one of the said pipes to the current-out-off device and an auxiliary pipe, a movable platform and valves under the control of the movements of the platform for opening and closing communication to the out-off device and to the brake, substantially as set forth.

5. In a controlling device for cars having air-brakes, a brake-controller, pipes leading to and from the controller, a pipe leading from the pipe leading to the controller, an auxiliary pipe leading to the pipe leading from the controller, a movable platform and valves under the control of the movements of the platform for opening and closing communication through the brake-controller and opening it through the auxiliary pipe when the platform is moved in one direction and for closing communication through the auxiliary pipe and opening it through the brake-controller when the platform is moved in the opposite direction substantially as set forth.

6. A controlling mechanism for electrically-propelled cars having air-brakes comprising a current-out-off device, an air head-pipe leading

therein, a movable platform and a valve in said pipe under the control of the movements of the platform for opening and closing communication from the air head-pipe to the current-out-off device, substantially as set forth.

7. In an electrically-propelled car having an air-brake, a brake-controller, a current-out-off device, a pipe leading to the brake-controller, a pipe leading from the brake-controller, a pipe leading from the first-named pipe to the out-off device, an auxiliary pipe leading from the out-off device to the pipe leading from the brake-controller, a valve located in the pipe leading from the brake-controller between the junction of the said pipe with the auxiliary pipe and the brake-controller, a valve located in the pipe leading to the out-off device between the junction of the auxiliary pipe therewith and the pipe leading to the brake-controller, a connection between the said valves whereby when one is open the other is closed, and a movable platform connected with the last-named valve for opening and closing the valve, substantially as set forth.

696,753. DIE FOR MAKING FORKS. SAMUEL D. ROBERTSON, New York, Pa. Filed Dec. 12, 1900. Serial No. 68,657. (No model.)

Claim.—1. A die for making forks and similar articles, the same comprising a body having a transverse cavity or groove for forming and shaping the head or back bar of the fork, and a series of longitudinal cavities or grooves communicating with said transverse cavity for forming and shaping the tines, said transverse and longitudinal cavities being bounded by cutting-walls, and the longitudinal cavities being separated by grooves or spaces of greater depth for receiving the cut-away portions of the plate.

2. Die for making forks and similar articles, the same comprising bodies each having a transverse cavity or groove for forming and shaping the head or back bar of the fork, and a series of longitudinal cavities or grooves communicating with said transverse cavity for forming and shaping the tines, said transverse and longitudinal cavities being bounded by cutting-walls, and the longitudinal cavities on one of said dies at least being separated by grooves or spaces of greater depth for receiving the cut-away portions of the plate.

3. A die for making forks and similar articles, the same comprising a body having a transverse cavity or groove for forming and shaping the head or back bar of the fork, and a series of longitudinal cavities or grooves communicating with said transverse cavity for forming and shaping the tines, said transverse and longitudinal cavities being bounded by cutting-walls, and the longitudinal cavities being tapered toward their outer ends to form the points of the tines and being separated by grooves or spaces of greater depth for receiving the cut-away portions of the plate.

4. A die for making forks and similar articles, the same comprising a body having a transverse cavity or groove for forming and shaping the head or back bar of the fork, and a series of longitudinal cavities or grooves communicating with said transverse cavity and having sloping or curved walls for forming and shaping the tines, said transverse and longitudinal cavities being bounded by cutting-walls, and the longitudinal cavities being separated by grooves or spaces for receiving the cut-away portions of the plate.

5. A die for making forks and similar articles, the same comprising a body having a transverse cavity or groove for forming and shaping the head or back bar of the fork, a cavity communicating with said transverse cavity at its middle portion for cutting out a portion to form the tang of the fork, and a series of longitudinal cavities communicating with the transverse cavity for forming and shaping the tines, all of said cavities being bounded by cutting-walls, and the longitudinal cavities being separated by grooves or spaces for receiving the cut-away portions of the plate.

696,754. FOLDING ICE-BOX. RALPH F. BOGGS, Lakeview, N. J. Filed Dec. 14, 1901. Serial No. 68,657. (No model.)

Claim.—1. A folding ice-box, comprising a collapsible box-like member provided with a folding lid, a flexible jacket adapted to cover said member and provided with a folding flap corresponding to said lid, and means for detachably securing said lid and said flap together, so that said

flap may be readily detached from said lid and said jacket may be easily removed from said box-like member.

2. A folding ice-box, comprising a collapsible box-like member having a folding lid provided with a knob, and a flexible jacket of non-conducting material for removably inclosing said member, said jacket having a loose flap provided with a hole for engaging said knob, the arrangement being such that said flap together with the lid of said box-like member is normally free to move relatively to said member, yet said jacket is readily removable from said member.

3. A folding ice-box, comprising a waterproof pan, side and end leaves mounted therein and flexibly secured to the bottom thereof, a flanged top provided with an opening and with heads for engaging said side and end members, and a folding lid flexibly mounted upon said top so as to cover said opening, said parts normally constituting a collapsible box-like member, and a jacket of non-conducting material for covering said box-like member, said jacket being provided with a loose flap corresponding to the lid of said box-like member and detachably secured to said lid so as to fold therewith, yet readily detachable therefrom so that said jacket can be removed from said box-like member.

4. A folding ice-box, comprising a waterproof pan provided with a drain-tube, folding leaves hinged directly to the bottom of said pan, a removable ice-grid normally resting on the bottom of said pan, and a detachable top provided with heads for temporarily securing said leaves together at the corners thereof, the arrangement being such that said grid may be removed, said leaves folded upon each other, said grid placed upon said leaves, and said top laid upon said grid, whereby all movable parts of said apparatus will occupy said pan and be drained simultaneously.

696,755. GRAIN-CRUSHER. HENRI ROSE and GEORGE ROSE, Paris, France. Filed Dec. 6, 1900. Serial No. 58,857. (No model.)

Claim.—1. In a grain-crushing machine, the outer, cylindrical casing, the movable bars in the said casing, said bars being placed close together and mounted to rock on journals, the drum rotatably mounted in the casing and having ribs on its periphery which rotate in close proximity to the movable bars in the casing, and means for separately adjusting and setting groups of the said bars, the said casing having an inlet for grain extending substantially the entire length of the enclosing drum and opening directly to the periphery of the latter, and the series of bars in the casing being wholly in advance of the grain-inlet, substantially as set forth.

2. In a grain-crushing machine, the combination with the outer casing, and the ribbed drum rotatably mounted therein, of the concentrically-disposed and parallel rock-shafts 10, mounted to the ends of the upper part of the casing, the arms 12 on the projecting ends of said rock-shafts, the links coupling said arms together in groups, means for opening and securing the coupled groups of arms, and the bars 11 placed close together on the respective rock-shafts, substantially as set forth.

696,756. JEWEL-SETTING MACHINE. WILLIAM EMMONS, Brighton, N. Y. Filed Nov. 6, 1901. Serial No. 51,281. (No model.)

Claim.—1. The combination of a spindle having a terminal enlargement, a coupling-head having a cylindrical socket and a longitudinal slot through its forward side to receive said enlargement and spindle, both said socket and slot opening at both ends of said coupling-head, and means for moving said coupling-head at right angles to the length of said spindle, substantially as set forth.

2. The combination of a spindle having a terminal enlargement, a coupling-head having a cylindrical socket and a longitudinal slot through its forward side to receive said enlargement and spindle, both said socket and slot opening at both ends of said coupling-head, means for moving said coupling-head at right angles to the length of said spindle, and means for intermittently actuating said coupling-head and spindle, substantially as set forth.

3. The combination of a blank or stock carrying device, a carrier equipped with tool-spindles and adapted to move at right angles to said device means for actuating said tool-spindles and a common coupling device between said tool-spindles and said actuating means for successively receiving said spindles, substantially as set forth.

4. The combination of a blank or stock carrying device or head-stock, a carrier equipped with tool-spindles and adapted to move at right angles to said head-stock, means for imparting such movement to said carrier, means for actuating said tool-spindles and a common coupling device comprising a cylindrical socket with a longitudinal slot therethrough, both said socket and slot opening at both ends, to connect up said socket successively with said tool-spindles, substantially as set forth.

5. The combination of a blank or stock carrying device or head-stock, a carrier equipped with tool-spindles, and adapted to move at right angles to said stock-carrying device, means for imparting such movement to said carrier a cam or intermittently-actuated lever for actuating said spindles and a common coupling device for successively effecting connection between said tool-spindles and said intermittently-actuated lever, substantially as set forth.

6. The combination of a stock or blank carrying device, a carrier equipped with tool-carrying spindles, and movable at right angles to said stock-carrying device, a gear-and-rack mechanism for actuating said carrier, means for actuating said tool-spindles and a common coupling device for successively effecting connection between said tool-spindles and said actuating means, substantially as set forth.

7. The combination of a stock or blank carrying device, a carrier equipped with tool-spindles and movable at right angles to said tool-carrying device, a gear-and-rack mechanism for actuating said carrier, and an intermittently-actuated lever for operating said spindles, substantially as set forth.

8. The combination of a stock or blank carrying device, a carrier having movement at right angles thereto, and equipped with tool-carrying spindles, an intermittently-actuated lever for said spindles, a coupling between said spindles and lever, and a rack-and-gear mechanism for said carrier, substantially as set forth.

9. The combination of a stock or blank carrying device, a carrier having an intermittent movement at right angles thereto and equipped with tool-spindles, means for imparting such movement to said carrier, means for actuating said tool-spindles, a coupling between said spindles and said means for actuating said spindles, and an intermittently-actuated dog or detent engaging said carrier, substantially as set forth.

10. The combination of a stock or blank holding device, a carrier having an intermittent movement at right angles thereto, and equipped with tool-spindles, an intermittently-actuated rack-and-gear mechanism for said carrier, a corresponding actuated dog or detent for said carrier, and means for actuating said tool-spindles, a coupling between said spindles and said means for actuating said spindles, substantially as set forth.

11. The combination of a stock or blank holder, a carrier equipped with tool-spindles having movement at right angles to said holder, a gear-and-rack mechanism for said carrier, a cam-actuated dog or detent for said carrier, and a cam-actuated lever for said tool-spindles, substantially as set forth.

12. The combination of a stock or blank holder, a carrier equipped with tool-spindles and having movement at right angles to said holder, means for imparting an intermittent rectilinear movement to said carrier, and means for transmitting an intermittent back-and-forth movement or stroke to said tool-spindles and a coupling device between said tool-spindles and the means for actuating said tool-spindles, substantially as set forth.

13. The combination of a carrier equipped with tool-spindles, an intermittently-actuated lever for actuating said spindles, means for imparting a rectilinear movement to said carrier and a coupling between said tool-spindles and lever, adapted to permit the lateral insertion thereto and the corresponding withdrawal therefrom, of said spindles, substantially as set forth.

14. The combination of a stock or blank holder, a movable and intermittently-actuated carrier equipped with tool-spindles and having movement at right angles with said holder, a cam-actuated lever adapted to control or transmit movement to said tool-spindles, a coupling forming connection between said tool-spindles and lever, and an intermittently-actuating device for said carrier, substantially as set forth.

15. The combination of a carrier equipped with tool-spindles and having a rack, a gear-wheel or pinion meshing with said rack, means for actuating said spindles, an additional pinion on the shaft of the first-named pinion, a toothed sector or quadrant meshing with said additional pinion, and means for actuating said tool-spindles, substantially as set forth.

16. The combination of a tool-spindle carrier, means for actuating the same, a dog or detent, adapted to engage said carrier, and having a right-angled arm, and a disk having cam projections upon the periphery adapted to engage said arm, and retract said dog or detent from said carrier, substantially as set forth.

17. The combination of a carrier having rectilinear movement, tool-spindles mounted in said carrier, springs arranged in connection with, and acting upon, said spindles, rollers secured upon said spindles, guide-rods secured to said carrier, said rollers having bifurcated portions engaging said guide-rods, and means for actuating said spindles, substantially as set forth.

18. The combination of a carrier, a spindle mounted in said carrier, a horizontal cutter, a base or support mounted in said spindle, a shaft bearing said cutter, and journaled in a support or case, a dog or pawl suitably supported upon said carrier, and gearing for actuating said cutter, said dog adapted to engage a pinion of said gearing as said spindle is actuated, substantially as set forth.

19. The combination of a carrier, a horizontal cutter suitably supported in a spindle of said carrier, gearing for actuating said cutter, and a triangular pivoted dog or pawl suitably supported upon said carrier and adapted to engage a pinion of said gearing as said spindle is actuated, substantially as set forth.

20. The combination of a carrier, a horizontal cutter suitably supported in a spindle of said carrier, gearing for actuating said cutter, a bracket or arm projecting from said carrier, a triangular dog or pawl pivoted upon said bracket and adapted to engage a pinion of said gearing, and having a pin or rod extending through a slot in said bracket, and engaged by a spring secured to said bracket, substantially as set forth.

21. In a machine of the character described, the combination of a spindle-carrier, a horizontal cutter secured upon a shaft having a beveled pinion secured thereto, a support for said shaft having an arm secured in a spindle of said carrier, a second shaft bearing also a beveled pinion geared to the first-named pinion and carrying a worm-wheel, a third shaft bearing a gear-wheel, and a spring-pressed triangular pivoted dog or pawl

carried by said bracket or support secured to said carrier, said dog or pawl adapted to engage said gear-wheel, substantially as set forth.

22. In a machine of the character described, the combination with a spindle of the tool-spindle carrier, of a jewel-holder comprising a tubular portion having a circular feeder at one end, and a spring-pressed pivoted gate or valve having an elongated slot therethrough receiving its pivot, and a notch in its lower end registering with the feeding-opening of said tubular portion, substantially as set forth.

23. The combination with a spindle of the tool-spindle carrier, of the jewel-holder comprising a tubular portion and a circular feeder having a pivoted valve or gate with an elongated slot therethrough for the reception of its pivot, and a spring with one end secured to said circular head and its other end connected to an extension of said gate or valve, substantially as set forth.

24. The jewel-holder comprising an outer tube or casing provided at one end with a head or feeder, and an inner conical tube, with one end adapted to fit into an enlargement of the feeding-opening of said head, and its opposite end having a screw-threaded enlargement engaging an internal screw-thread of one end of said outer tube or casing, substantially as set forth.

25. The combination with a spindle of the tool-spindle carrier, of a jewel-holder comprising a tubular portion having a circular head or feeder at one end, a pivoted spring-pressed gate or valve having a notch in its lower edge adapted to register with the feeding-opening of said head, and a stop projecting from the edge of said head and adapted to engage an extension of said gate or valve, substantially as set forth.

696,757. SHUNT FOR ELECTRICAL INSTRUMENTS. MAURICE C. RYFORD, Schenectady, N. Y. Assignor to General Electric Company, a Corporation of New York. Filed Sept. 5, 1901. Serial No. 74,377. (No model.)

Claim.—1. A shunt for an electrical measuring instrument having between its terminals a resistance-plate adapted for the reception of a fusible conductor.

2. A permanent shunt for an electrical measuring instrument having a resistance-plate formed of a diffusible-fusible metal to which a readily-fusible metal has been applied whereby the resistance may be readily and accurately graduated.

3. A shunt for an electrical measuring instrument containing a resistance-strip of diffusible-fusible metal having its conductivity increased by an application of a readily-fusible metal.

4. A shunt for an electrical measuring instrument having a resistance-plate containing recesses for a more easily fusible metal.

5. A shunt for an electrical measuring instrument having a resistance-plate containing one or more transverse grooves.

6. A shunt for an electrical measuring instrument having a transversely-grooved resistance-plate to which an easily-removable conductor has been applied to vary its resistance.

7. A shunt for an electrical measuring instrument containing a plurality of transverse corrugations to serve as recesses for a more readily fusible metal such as solder.

696,758. COMPOUND TOOL. CHARLES SAWYER, Washington, D. C. Assignor of one-half to Andrew Shtinsky, Washington, D. C. Filed June 22, 1901. Serial No. 68,693. (No model.)

Claim.—1. In a compound tool the combination with a handle of a sliding jaw pivoted at one end thereof and provided with a bifurcated wrench at one end, and an end tool at the other, the whole arranged whereby the jaws of said wrench spring over and straddle said handle when the end tool is swung into position, substantially as described.

2. In a compound tool the combination with a handle of a sliding jaw pivoted thereto, and provided with a bifurcated wrench at one end thereof and an end tool at the other, notches in said handle, means on the handle for engaging the same for limiting the movement of said jaw, the whole arranged whereby the jaws of said wrench spring over and straddle said handle when the end tool is swung into position, substantially as described.

696,759. STOP-HOLDER. PHILIP BURRIE, Chicago, Ill. Original application filed Aug. 13, 1901. Serial No. 72,101. Divided and this application filed Nov. 20, 1901. Serial No. 84,068. (No model.)

Claim.—1. The combination with the headpiece 1, having vertical guides in its ends, an aperture at one end and a corresponding locking-lip at the other end; of the wire ball 2, having right-angle portions at the ends to engage the headpiece and guides, one of the ball ends having a member to pivotally engage the aperture in the headpiece, and a hook member at the other end to engage the locking-lip on the opposite end of the headpiece, and a finger-manipulated means for pulling the ball into or out of its locked position, as specified.

2. The combination with the headpiece 1, having a plurality of apertures in one end, and a plurality of cooperating locking-lips at the other end, said lips having their opening edges beveled inward and downward, the headpiece having a stop-bearing surface on its lower edge; of the ball 2, adapted to engage the stop and hold it against the bearing-surface, said ballpiece having upturned ends, one of which has a pinlike member to engage either one of the apertures in the headpiece, and a hook at the other end to engage either one of the locking-lips, and means for pulling the hook end of the ball onto or off of the locking-lip, all substantially as shown and for the purpose described.

3. In an appliance of the character described, a headpiece having a stop-end on its under face extending its length, and a vertical guide at each end, an aperture at one end, a locking-lip at the other end cooperating with the aperture, a spring-rod ball adapted to pass under the stop-fold and hold it up against its seat on the headpiece, said ball having right-angle ends adapted to extend up between the end guides, one of the ends having a pivot member adapted to detachably engage the aperture in one end of the headpiece, and its other angle member having an eye and a hook, said hook being arranged to engage the locking-lip at the corresponding end of the headpiece, and the wire loop 5, adapted to straddle the upper edge of the headpiece and having a pivotal connection with the eye part of the ball 2, all being arranged substantially as shown and for the purpose described.

696,760. FEED-BAG. DIKE SCHUBERT, Hoboken, N. J. Filed Dec. 22, 1901. Serial No. 88,889. (No model.)

Claim.—The combination with a feed-bag, of a transversely-arranged bowed spreader secured to the rear wall of the bag near the lower end thereof, and a shield secured at its upper end to the upper rear edge of said bag, at its sides with the sides of the bag and extending downward into line with the said spreader whereby the lower end of the guard is held away from the rear wall of the bag, substantially as described.

696,761. BROWN-MACHINE. HERMAN M. SCHWARTZ, Northampton, Mass. Assignor to Florence Manufacturing Company, Northampton, Mass., a Corporation of Massachusetts. Filed June 22, 1900. Serial No. 21,106. (No model.)

Claim.—1. In a brush-machine, the combination, with a bristle-feeding hopper, and mechanism for agitating the contents of the hopper, of

means for supporting the bristle block below the hupper and changing its position while being filled.

2. In a brush-machine, the combination with a bristle-feeding hopper, and mechanism for agitating the hopper, of means for supporting the bristle-block below the hopper and changing its position while being filled.

3. In a brush-machine, the combination with a bristle-feeding hopper, and a bristle-stirrer, working within the said hopper, of a support below the hopper to receive the bristle-block.

4. In a brush-machine, the combination with a bristle-filling hopper, and a bristle-stirrer working within the said hopper, of means for supporting the bristle-block below the hopper and changing its position while being filled.

5. In a brush-machine, the combination with a bristle-feeding hopper, and mechanism for agitating the hopper, of a bristle-stirrer working within the hopper, and a support below the hopper to receive the bristle-block.

6. In a brush-machine, the combination with a bristle-feeding hopper, and mechanism for agitating the-hopper, of a bristle-stirrer working within the hopper, and means for supporting the bristle-block below the hopper and changing its position while being filled.

7. In a brush-machine, the combination with a bristle-feeding hopper, and mechanism for agitating the contents of the hopper, of a bristle-block support below the hopper and means for moving said support to shift the position of the bristle-block while being filled.

3. In a brush-machine, the combination with a bristle-filling hopper, and mechanism for agitating the hopper, of a bristle-block support below the hopper, and means for moving said support to shift the position of the bristle-block while being filled.

2. In a brush-machine, the combination with a bristle-feeding hopper, and a bristle-cirrer working within the said hopper, of a bristle-block support below the hopper, and means for moving said support to shift the position of the bristle-block while being filled.

10. In a brush-machine, the combination with a bristle-feeding hopper, mechanism for agitating the hopper, and a bristle-stirrer working within the hopper, of a bristle-block support below the hopper, and means for moving said support to shift the position of the bristle-block while being filled.

11. In a brush-machine, the combination with a bristle-filling hopper and means for supporting a bristle-block in position to be filled, of a rotary stirrer within the hopper, and means for traversing the said stirrer.

12. In a brush-machine, the combination with a bristle-filling hopper, and a support for a bristle-block, of a rotary stirrer working within the hopper, supports for the said stirrer, and means for moving the said supports transversely of the hopper to traverse the stirrer in the latter.

13. In a brush-machine, the combination with a bristle-feeding hopper, and means for supporting a bristle-block of a rotary stirrer working within the hopper, supports for the said stirrer and means for moving the said supports oppositely with relation to each other and transversely of the hopper to traverse the stirrer in the latter.

14. In a brush-machine, the combination with a bristle-filling hopper, a support for a bristle-block, and a receptacle for the loose bristles, of a conveyor for returning the said loose bristles to the hopper.

15. In a brush-machine, the combination with a bristle-feeding hopper, and a support for a bristle-block, of a receptacle for loose bristles, the said receptacle having an inclined bottom and a conveyor for returning the bristles from the said receptacle to the hopper.

16. In a brush-machine, the combination with a bristle-filling hopper, a support for a bristle-blank, and a mechanism for the loose bristles, of a moving conveyor having teeth to take the said loose bristles from the said receptacle and return them to the hopper.

17. In a brush-machine, the combination with a bristle-feeding hop-

per, and a support for a bristle block, of a grid or grating adjacent the said support and adapted to contain the bristle-blocks while being handled by the workman, and a receptacle below the said support and grid or grating to receive the loose bristles.

18. In a brush-machine, the bristle-feeding hopper, means to agitate the same vertically, and a support for the bristle-block, combined with a bristle-cirrer rotating within the hopper, supports for the said cirrer independent of the hopper, and means for moving the said supports to traverse the rotary cirrer transversely with relation to the vertically-moving hopper.

896,762. AUTOMATICALLY-OPERATED MUSICAL INSTRUMENT. REBERT & SHAPIR, Fairfield, Conn., assignors to Oliver Tarney, Fairfield, Conn. Filed Aug. 20, 1931. Serial No. 73,206. (No model.)

*Claim.—*1. Is a pneumatically-operated manual instrument, the combination with an exhaust-chamber and diaphragm in the bottom of said chamber which control the operation of the primary valve mechanism, of air-supply ducts whose lower mouths are beneath said diaphragm and whose upper extremities are beneath the paper containing the sound-producing characters, exhaust-ducts communicating between said exhaust-chamber and said air-supply ducts, and coveas extending across the air-supply ducts, designed to place said exhaust-ducts for regulating the effective caliber thereof, and whereby the supply of air beneath said diaphragm may be controlled, substantially as described.

2. In a pneumatically-operated medical instrument, the combination with an exhaust-chamber and diaphragm in the bottom of said chamber which control the operation of the primary valve mechanism, of air-supply ducts whose lower mouths are beneath said diaphragm, and whose upper extremities are beneath the paper containing the sound-producing characters, exhaust-ducts between said exhaust-chamber and said air-supply ducts, and servos passed through the walls of said air-supply ducts and across the same so as to register with the mouths of said exhaust-ducts, whereby a portion of each of said air-supply ducts is designed to serve as an exhaust-duct at predetermined times, substantially as described.

3. In a pneumatically-operated musical instrument, the combination with an exhaust-chamber and diaphragm in the bottom of said chamber which control the operation of the primary valve mechanism, of air-supply ducts whose lower mouths are beneath said diaphragm, and whose upper extremities are beneath the paper containing the sound-producing characters, exhaust-ducts communicating with said exhaust-chamber and air-supply ducts, and means traversing said air-supply ducts for controlling the effective caliber of said exhaust-ducts, whereby the portions of said air-supply ducts beneath said controlling means is designed at times to serve as an exhaust-duct, and also whereby the atmospheric pressure upon said diaphragm may be regulated, substantially as described.

696,768. TARGET-TRAP. LOUIS A. SUTHERLAND, Kansas City, Mo.
Filed Jan. 16, 1901. Serial No. 42,424. (No model.)

(Claim.— 1. Is a target-trap, a frame, a carrier-arm pivotally mounted intermediate to and upon said frame, a spring connected at one end to said frame and at the other to one end of said arm, a carrier mounted on the other end of said arm, in combination with a stop pivotally mounted upon said arm and provided with a curved or beveled rear surface and an engaging front surface, said stop provided with a shoulder on the rear surface thereof arranged to engage said arm to limit the rocking movement of said stop in one direction, and a movable latch carried by said frame with which said stop cooperates when said arm is rocked against the action of said spring into retracted position preparatory to projecting a target to lock said arm in such position, and means for withdrawing

said latch from engaging relation with said stop to release said arm, as and for the purpose set forth.

2. In a target-trap, a carrier-arm pivotally mounted intermediate the ends thereof, a carrier connected to one end of said arm, a spring connected to the other end of said arm for actuating the same, and a stop carried by said arm, in combination with an electromagnet, a pivoted armature therefor, a movable frame arranged to be engaged and disengaged by said armature, and an abutment carried by said frame with which said stop cooperates, as and for the purpose set forth.

3. In a target-trap, a carrier-arm pivotally mounted intermediate the ends thereof, a carrier connected to one end of said arm, a spring connected to the other end of said arm for operating the same, and a stop carried by said arm, in combination with an electromagnet, a pivoted armature therefor, a movable frame arranged to be engaged and disengaged by said armature, an abutment carried by said frame and arranged to be engaged by said stop, as and for the purpose set forth.

4. In a target-trap, a carrier-arm, means for actuating the same, and a stop pivotally mounted on said arm, in combination with a roller with which said stop cooperates to lock said arm in retracted position, an electromagnet, and a movable armature therefor, said armature operating to detachably maintain said roller in engaging relation with respect to said stop, as and for the purpose set forth.

5. In a target-trap, a carrier-arm pivotally mounted intermediate the ends thereof, a carrier connected to one end of said arm, a spring connected to the other end of said arm for actuating the same, and a stop carried thereby, in combination with a yielding frame having an engaging part with which said stop cooperates, pivotally-mounted levers arranged to engage said frame, an electromagnet, a movable armature therefor, said armature arranged to engage and release said levers, as and for the purpose set forth.

696,764. LEG-GUARD. BENJAMIN F. SEYER, BAL., PA. Filed July 27, 1901. Serial No. 66,576. (No model.)

Claim.—1. A guard for protecting the leg of the wearer from the impact of a blow, consisting of a curved shield portion, and stay means secured to the side of said shield portion over the concave surface thereof as to be slack, for the purpose of permitting the leg of the wearer to partially set into the concavity of said shield, and form a space between said stay means and the concave surface of the shield, and means for securing said guard to the leg of the wearer.

2. A guard of the character described, comprising a shield, a stay-piece shorter than the inner surface of said shield and secured to said shield over the inner side thereof, whereby a space is formed between the stay and the inner surface of said shield, and means for securing said guard to the wearer.

3. A leg-guard of the character described, comprising a curved shield, stay or stays shorter than the inner periphery of said shield and secured over the inner side thereof, whereby a space is formed between said stay or stays and the concave surface of said shield, and means for attaching said shield to the leg.

4. A leg-guard of the character described, comprising a curved shield, stay or stays of plant material shorter than the inner periphery of said shield and secured over the inner side thereof at or near its opposite edges, whereby a space is formed between said stay or stays and the concave surface of said shield, and means for securing said shield to the leg.

5. A leg-guard of the character described, consisting of a curved rigid shield portion having attached thereto at or near the edges thereof an inner plant portion that is adapted to rest against the leg, and means for attaching the guard to the leg; the said inner plant portion being less in length than the width of the blank from which the shield portion is made, substantially as described.

696,765. ACETYLENE-GAS GENERATOR. FAYEL BROSSE, STERLING, ILL. Filed Dec. 22, 1899. Renewed Oct. 2, 1901. Serial No. 77,461. (No model.)

Claim.—1. In an acetylene-gas generator, a long and narrow carbide-holder presenting a small area in cross-section of exposed surface for the carbide and formed of an imperforate body an open top and a closed and weighted bottom, means for maintaining the carbide-holder in a perpendicular position with its top above the surface of the water, and means for releasing the carbide-holder and permitting it to be submerged in the water and aided in its descent and held when submerged in a vertical position by the weighted bottom, substantially as described.

2. In an acetylene-gas generator, a desired number of long and narrow carbide-holders each presenting a small area in cross-section of exposed surface for the carbide and each formed of an imperforate body an open top and a closed and weighted bottom and normally held with the open top above a body of water contained in the generating-chamber, and means for automatically releasing each carbide-holder to permit it to descend and be submerged in the water, whereby the water enters at the top only and acts only on a small area of exposed carbide, substantially as described.

3. In an acetylene-gas generator, a desired number of long and narrow carbide-holders, each holder presenting a small area in cross-section of exposed surface for the carbide and each formed of an imperforate body an open top and a closed and weighted bottom and normally held with the open top above the surface of a body of water in the generating-chamber, a correspondingly-shaped guiding-well for each carbide-holder in which the holder is received and held vertically and guided, and means for releasing each holder from its raised position in its well to permit it to descend and be assisted in its descent and submerged in the body of water in the generating-chamber and held in a vertical position when submerged by the weighted bottom for the admission of water at the open top only, substantially as described.

4. In an acetylene-gas generator, a desired number of long and narrow carbide-holders, each holder presenting a small area in cross-section of exposed surface for the carbide and each formed of an imperforate body an open top and a closed and weighted bottom and normally held with the open top above the surface of a body of water in the generating-chamber, a correspondingly-shaped guiding-well for each carbide-holder in which the holder is received and held vertically and guided, means for supporting the carbide-holders in the wells in a raised position, and means for releasing the carbide-holders successively and at intervals from the raised position to permit them to descend and be assisted in their descent and submerged in the body of water in the generating-chamber and held in a vertical position when submerged by the weighted bottom for the admission of water at the top of each holder only, substantially as described.

5. In an acetylene-gas generator, a rotatable bell, a main shaft extending up through the generator beneath the bell and on which the bell is mounted and by which it may be rotated, means for limiting the upward movement of the bell on the shaft, and means beneath the bell for automatically imparting rotation to the main shaft at desired intervals, substantially as described.

6. In an acetylene-gas generator, a casing containing a body of water, a rotatable bell arranged in the casing, means for intermittently imparting partial rotation to the bell, a desired number of carbide-holders located in juxtaposition side by side circumferentially around the interior of the casing at its upper end, each carbide-holder open at one end and

with the open end normally supported under the bell above the body of water, means for supporting the carbide-holders individually, and means actuated by the partial rotation of the bell for automatically and successively releasing the carbide-holders and permitting them to be submerged in the water, substantially as described.

7. In an acetylene-gas generator, a casing containing a body of water, a rotatable bell arranged in the casing, means for intermittently imparting partial rotation to the bell, a desired number of carbide-holders located in juxtaposition side by side circumferentially around the interior of the casing at its upper end, each carbide-holder open at one end and with the open end normally supported under the bell above the body of water, a guiding-wall for each carbide-holder in which it is received and guided, each wall containing a single carbide-holder, means for supporting the carbide-holders individually in the walls, and means actuated by the partial rotation of the bell for automatically and successively releasing the carbide-holders and permitting them to be submerged in the water, substantially as described.

8. In an acetylene-gas generator, a casing containing a body of water, a bell arranged in the casing, a desired number of guiding-wells within the casing under the bell and extending into the body of water contained in the casing, carbide-holders open at the top and slidably arranged in the wells with the active surface of the carbide in the holders above the surface of the water, supports for maintaining the carbide-holders so arranged, a trigger device adapted to actuate the supports and release the carbide-holders, means for automatically operating the trigger device to permit the carbide-holders to be submerged in the water, and means for maintaining the carbide-holders when released and submerged in a stationary upright position while the action of generation takes place, substantially as described.

9. In an acetylene-gas generator, a casing containing a body of water, a bell arranged in the casing, a desired number of circumferentially-disposed and perpendicularly-arranged guiding-wells within the casing under the bell and extending into the body of water contained in the casing, carbide-holders open at the top and arranged in the wells with the active surface of the carbide in the holders above the surface of the water, removable supports for maintaining the carbide-holders so arranged, a trigger device adapted to actuate the supports and release the carbide-holders, a rotatable member adapted to successively engage the trigger devices and remove the supports and permit the carbide-holders to be submerged in the water, and means for automatically imparting rotation to the rotatable member at desired intervals, substantially as described.

10. In an acetylene-gas generator, a casing containing a body of water, a gas-generator chamber, a desired number of guiding-wells circumferentially disposed and perpendicularly arranged within the gas-chamber under the bell and extending into the body of the water, carbide-holders open at the top and slidably arranged in the wells with the active surface of the carbide in the holders above the surface of the water, removable supports for maintaining the carbide-holders so arranged, a trigger device adapted to actuate the supports and release the carbide-holders, an engaging member carried by the rotatable bell adapted to successively engage the trigger devices and remove the supports and permit the carbide-holders to be submerged in the water, and means for automatically imparting rotation to the bell at desired intervals, substantially as described.

11. In an acetylene-gas generator, a desired number of guiding-wells circumferentially disposed and perpendicularly arranged within the gas-chamber and extending into the body of water, carbide-holders open at the top and slidably arranged in the wells with the active surface of the carbide in the holders above the surface of the water, movable supports for the carbide-holders, a rotatable bell arranged in the generator, means carried by the bell for actuating the movable supports of the carbide holders, a main shaft on which the bell is mounted and by which it may be rotated, and means for automatically imparting rotation to the main shaft at desired intervals, substantially as described.

12. In an acetylene-gas machine, a gas-generator having a generating-chamber containing a body of water, a desired number of long and narrow carbide-holders arranged in the chamber, each holder presenting a small area in cross-section of exposed surface for the carbide and each formed of an impermeable body as open top and a closed and weighted bottom and normally held with the open top above the surface of a body of water in the generating-chamber, means for supporting each carbide-holder vertically in its normal position, a gasometer, means for conveying gas from the generating-chamber to the gasometer, and means automatically operated at a predetermined point of consumption of gas in the gasometer for releasing the carbide-holders from their raised position to permit them to descend and be assisted in their descent and submerged in the body of water in the generating-chamber and held vertically when submerged by the weighted bottom for water to enter the holder at the top only, substantially as described.

13. In an acetylene-gas machine, a gas-generator, a rotatable bell arranged in the generator, a desired number of carbide-holders open at one end and with the open end normally supported under the bell above a body of water contained in the generator, means for supporting the carbide-holders, a gasometer, means for conveying gas from the generator to the gasometer, means for intermittently imparting partial rotation to the bell into operation when the gas in the gasometer reaches a predetermined point of consumption, and means for automatically releasing the carbide-holders and permitting them to be submerged in the water actuated by the partial rotation of the bell, substantially as described.

14. In an acetylene-gas generator, a carbide-holder having an impermeable body as open top and a closed and weighted bottom, with the body of greatly-increased length as compared with its width, forming an open-top closed chamber for receiving the carbide and held in a vertical position by the weighted bottom permitting the free carbide to be exposed to the action of water from the top only with a small area of surface exposure, a generator-bell, and a well for the holder located beneath the generator-bell and having an open top and bottom and having the holder releasably supported in the upper portion of the well to descend therein when released and be maintained in perpendicular position in its descent with the open top uppermost, substantially as described.

15. In an acetylene-gas generator, a generating-chamber partially filled with water, a vertical well within the generating-chamber having an open top and bottom for the admission of water to its interior from the bottom, and a carbide-holder having an impermeable body as open top and a closed bottom with the body of an increased length as compared with its width, forming an open-top closed chamber for receiving carbide and means for supporting the carbide-holder in the well with its bottom projecting into the water of the well, the water to form a seal between the body of the holder and the wall of the well and prevent the downward flow of generated gas, substantially as described.

16. In an acetylene-gas generator, a generating-chamber partially filled with water, a vertical well within the generating-chamber having an open-top and bottom for the admission of water to its interior from the bottom, a carbide-holder having an impermeable body as open top and closed bottom with its body of increased length as compared with its width, forming an open-top closed chamber for receiving carbide and inserted in the upper portion of the well, means for supporting the holder in the well with its bottom projecting into the water of the well forming a water seal against the downward flow of generated gas, and means for releasing the holder to descend and be submerged in the water of the well to permit the water to enter the holder at the top, whereby the gas first generated will pass to the bottom of the holder and fill the interstices between the particles of carbide in the holder and exert an upward pressure in the holder, substantially as described.

17. In an acetylene-gas generator, a generating-chamber partially filled with water, a desired number of vertical wells within the generating-chamber, each provided with a hinged flap or cover for the top and each having an open top and bottom for the admission of water to its interior from the bottom, a carbide-holder for each well, each carbide-holder having an impermeable body as open top and a closed bottom with its body of an increased length as compared with its width, forming an open-top closed chamber for receiving carbide and inserted in the upper portion of its well, means for supporting each carbide-holder in the upper portion of its well with its bottom projecting into the water of the well, and means for releasing each holder from its raised position and permitting it to descend to the lower portion of the well and be submerged in the water therein, whereby the upward pressure of the gas through the confined space will remove the residuum and the hinged covers will prevent the discharge from entering the adjoining wells and protect the carbide of the holders therein from the injurious effect of the discharge, substantially as described.

18. In an acetylene-gas machine, the combination of a generator comprising an outer casing for water and provided with a bottom inclining toward the center, a pipe rising from the apex of the bottom and terminating beneath the gasometer-bell, a rotatable gasometer-bell removably mounted on an upright shaft and comprising an outer casing and a central depending inner casing secured to the top and extending downward into the water and forming a chamber around the upper end of the pipe, and a depending guide from the gasometer-bell surrounding the top of the central pipe for guiding the movements of the bell, substantially as described.

19. In an acetylene-gas machine, the combination of an angle-iron rod arranged outside of the gasometer-casing and suspended in a vertical position from the gasometer-bell and having a slot through one of its flanges and a pin on the other crossing in front of the slot, a ratchet-wheel, a pawl engaging the ratchet-wheel, a bent lever carrying the pawl and having one arm double and the double arm straddling the ratchet-wheel and provided with a hole through the double arm for mounting the lever on the shaft of the ratchet-wheel for a pivot to be engaged in action by the pin in the downward movement of the rod and curving downward on its pivot

and to be engaged by the lower end of the slot in the rod in the upward movement of the rod and carried to its normal position when at rest, substantially as described.

20. In an acetylene-gas machine, a ratchet-wheel mounted on a shaft and secured thereto, a bent lever having one arm double and the double arm straddling the ratchet-wheel and carrying a pawl to engage with the teeth of the ratchet-wheel and advance the wheel when the lever is swung or turned downward, the double arm of the bent lever being provided with a hole between the end and the angle for mounting the lever on the shaft of the ratchet-wheel as a pivot, the ratchet-wheel shaft extending horizontally to a point beneath the generator and provided with a beveled gear at its inner end, a vertical shaft extending upward through the generator within a central pipe therein and adapted to engage at its upper end the bell of the generator so as to rotate the same, a beveled gear near the lower end of the vertical shaft to engage with the bevel-gear of the horizontal shaft for imparting rotation to the vertical shaft from the horizontal shaft, and a pawl pivoted to a fixed point for preventing the ratchet-wheel from turning back while the bent lever is being drawn to its initial position, substantially as described.

21. In a gas-generator, the combination of a rotatable generator-hell having in its top a central hole for the passage of a main or driving shaft end, and a main or driving shaft for rotating the hell and on the upper end of which the hell is removably mounted to permit its withdrawal for recharging the generator, leaving the shaft in position in the generator, substantially as described.

696,766. ENGINE. FRANK E. BLUMBERG, Westmount, Canada, assignor of one-half to the North West Shoe Company, Limited, Montreal, Canada, a Corporation. Filed Oct. 20, 1902. Serial No. 34,772. (No model.)

Claim.—1. The combination of a shaft, a stationary part located adjacent to said shaft, a pair of partitions each in steam-tight contact at one end with the side of said stationary part adjacent to said shaft, means in relative relation with the shaft and forming in conjunction with said partitions and stationary part an expandable chamber, and an expandable-fluid supply to and exhaust from said chamber.

2. The combination of a shaft, a stationary part located adjacent to said shaft, a pair of partitions each in steam-tight contact at one end with the side of said stationary part adjacent to said shaft, means constantly free of said stationary part and in relative relation with the shaft and forming in conjunction with said partitions and stationary part an expandable chamber, and an expandable-fluid supply to and exhaust from said chamber.

3. The combination with the cylinder of an engine and a shaft extending therethrough, of an eccentric mounted upon and rotatable with said shaft, a series of partitions, each partition being in steam-tight contact at its sides with the interior of the cylinder and the eccentric respectively, an expandable-fluid supply to and exhaust from the space between the partitions, and means for controlling said expandable fluid to be supplied to said spaces successively, substantially as and for the purpose set forth.

4. The combination with the cylinder of an engine and a shaft extending therethrough, of an eccentric mounted upon and rotatable with said shaft, a series of pairs of partitions, each partition being in steam-tight contact at its sides with the interior of the cylinder and the eccentric respectively, an expandable-fluid supply to and exhaust from the alternate spaces between the adjacent pairs of said partitions, substantially as and for the purpose set forth.

5. The combination with the cylinder of an engine and shaft extending therethrough, of an eccentric mounted upon and rotatable with said shaft, a series of pairs of partitions, each partition being in steam-tight contact at its sides with the interior of the cylinder and the eccentric respectively, an expandable-fluid supply to and exhaust from the alternate spaces between the adjacent pairs of said partitions and means for controlling said expandable fluid to be supplied to said spaces successively, substantially as and for the purpose set forth.

6. The combination with the cylinder of an engine and a shaft extending therethrough, of an eccentric mounted upon and rotatable with said shaft, a series of pairs of flexible partitions, said pairs being disposed equidistant from one another and each partition being in steam-tight contact at its ends with the interior of the cylinder and the eccentric respectively, an expandable-fluid supply to and exhaust from the space between the said pairs of partitions, and means for controlling said expandable fluid to be supplied to said spaces successively, substantially as and for the purpose set forth.

7. The combination with the cylinder of an engine and a shaft extending therethrough, of an eccentric mounted upon and rotatable with said shaft, a series of pairs of blades, said pairs being disposed equidistant from one another, and each blade being pivotally connected at one end to the interior of said cylinder and bearing at its other end loosely upon the eccentric, an expandable-fluid supply to and exhaust from the space between said pairs of blades, and means for controlling said supply to come same to be supplied to said spaces successively, substantially as described and for the purpose set forth.

8. The combination with the cylinder of an engine and a shaft extending therethrough, of an eccentric mounted upon and rotatable with said shaft, said eccentric consisting of an offset portion of the shaft, a hub mounted loosely upon said offset portion, and an annulus mounted rigidly upon said hub, said annulus being of a width to closely fit the ends of said cylinder; a series of pairs of blades, said pairs being disposed equidistant from one another, and each blade being pivotally connected at one end to the interior of said cylinder and bearing at its other end loosely upon the eccentric, an expandable-fluid supply to and exhaust from the space between said pairs of blades, and means for controlling said fluid supply to come same to be supplied to said spaces successively, substantially as described and for the purpose set forth.

9. The combination with the cylinder of an engine and a shaft extending therethrough, of an eccentric mounted upon and rotatable with said shaft, said eccentric consisting of an offset portion of the shaft, a hub mounted loosely upon said offset portion, and an annulus mounted rigidly upon said hub, said annulus being of a width to closely fit the ends of said cylinder; a series of pairs of blades, said pairs being disposed equidistant from one another, and each blade being pivotally connected at one end to the interior of said cylinder and bearing at its other end loosely upon the eccentric, an expandable-fluid supply to and exhaust from the space between said pairs of blades, and means for controlling said fluid supply to come same to be supplied to said spaces successively, substantially as described and for the purpose set forth.

696,767. ENGINE. FRANK E. BLUMBERG, Westmount, Canada, assignor of one-half to the North West Shoe Company, Limited, Montreal, Canada, a Corporation. Filed Jan. 2, 1901. Serial No. 41,896. (No model.)

Claim.—1. In an engine the combination with a shaft of an expandable chamber consisting of a wall stationary relatively to said shaft, a flexible intact wall between said stationary wall and said shaft and hinged at two of its opposite sides to said stationary wall, means for closing the space between the stationary wall and the other side edges of said flexible wall, an expandable-fluid supply to and exhaust from said expandable chamber and means for relatively connecting said flexible wall to said shaft, substantially as described.

2. In an engine the combination with a shaft of an expandable chamber consisting of a wall stationary relatively to said shaft, a flexible intact wall between said stationary wall and said shaft and hinged at two of its opposite sides to said stationary wall, means for closing the space between the stationary wall and the other side edges of said flexible wall, an expandable-fluid supply to and exhaust from said expandable chamber and an eccentric carried by said shaft to receive from said flexible wall

and transmit to said shaft the thrust due to the expansion of said expansible chamber substantially as described.

3. An engine comprising a casing; a pair of heads closing the ends of said casing; a shaft extending through said casing; a portion of the shaft within said casing being offset; a series of pairs of blades pivotally connected at one side edge of each to the interior of said casing, the opposite side edges of the blades of each pair overlapping one another; and the other side edges of said blades being in contact with said heads; an intermediary between the offset portion of said shaft and each pair of blades, and an expansible-fluid supply to and exhaust from the space between each pair of blades and the portion of the casing covered thereby, substantially as described.

4. An engine comprising a casing of interior hexagonal form and recessed at its alternate angles and a pair of heads closing the ends of said casing; a shaft extending through said casing; a portion of the shaft within said casing being offset; a series of pairs of blades pivotally connected at one side edge of each to the interior of said casing at the other angles, the opposite side edges of the blades of each pair overlapping one another and the other side edges of said blades being in contact with said heads; the blades adjacent to the shaft being each formed with a head projecting toward the overlapping blade; an intermediary between the offset portion of said shaft and each pair of blades, and an expansible-fluid supply to and exhaust from the space between each pair of blades and the portion of the casing covered thereby, substantially as described.

5. An engine comprising a casing, a shaft extending through said casing, roller-bearings for said shaft in the walls of said casing, a motive-fluid supply to and exhaust from said casing, an automatic cut-off valve carried by the shaft for controlling the supply of said motive fluid, means for yieldingly connecting said cut-off valve to said shaft to accommodate the vibration of said shaft in its roller-bearings, means for causing said motive fluid to rotate said shaft, substantially as described.

6. In an engine the combination with the frame thereof, a shaft extending through said frame, roller-bearings for said shaft in said frame, a steam-chest, a cylindrical valve having a steam-port and mounted loosely upon said shaft for controlling the supply of steam from said steam-chest to said engine, and a feather connecting said valve to said shaft, substantially as described, and for the purpose set forth.

7. In an engine the combination with the frame thereof, a shaft extending through said frame, roller-bearings for said shaft in said frame, a steam-chest, a cylindrical valve having a steam-port leading at one end from the perimeter thereof and mounted loosely upon said shaft for controlling the supply of steam from said steam-chest to said engine, a feather connecting said valve to said shaft, an annular slide-valve having a port to register with and control the port in said cylindrical valve, a sleeve fitting over said shaft adjacent to said cylindrical valve and having its interior of increased diameter from the end thereof adjacent to said cylindrical valve to within a short distance of the other end thereof, means for connecting said sleeve to said slide-valve, and means connected to the shaft and to said sleeve and actuated by centrifugal force to rotate said sleeve upon said shaft, substantially as described and for the purpose set forth.

8. In an engine the combination with the steam-chest and a cylindrical valve having a port therein leading from the perimeter thereof for controlling the steam-supply from said steam-chest to said engine of an annular slide-valve encircling the portion of said valve having said port therein, said annular slide-valve having a port to register with and control said steam-supply-port, and means under the control of a rotating part of said engine for causing said annular slide-valve to slide over the surface of said cylindrical valve, substantially as described and for the purpose set forth.

9. In an engine the combination with the frame thereof, a shaft extending through said frame, a steam-chest, a cylindrical valve having a steam-port leading at one end from the perimeter thereof and an exhaust-port leading from the engine side to the opposite end thereof, said valve being mounted upon said shaft for controlling the supply of steam from said steam-chest to said engine, an annular slide-valve having a port to register with and control the steam-port in said cylindrical valve, a sleeve fitting over said shaft adjacent to said cylindrical valve, a series of bridge-pieces connecting said sleeve to said slide-valve, a cap for closing the outer end of the valve-chamber containing said cylindrical valve and slide-valve and having an exhaust-passage leading therefrom, and means connected to the shaft and to said sleeve and actuated by centrifugal force to rotate said sleeve upon said shaft, substantially as described and for the purpose set forth.

696,768. ENGINE. FRANK E. SUMNER, Westmount, Canada, assigner of one-half to the North West Shoe Company, Limited, Montreal, Canada, a Corporation. Filed Oct. 15, 1904. Serial No. 74,702. (No model.)

Claim.—1. An engine comprising a casing; a pair of heads closing

the ends of said casing; a shaft extending through said casing; a pair of blades pivotally connected at one side edge of each to the interior of said casing, the opposite side edges of said blades overlapping one another; a link-plate joining the overlapping edges of said blades and the other side edges of said blades being in contact with said heads; an intermediary between the said shaft and said blades, and an expansible-fluid supply to and exhaust from the space between said blades and the portion of the casing covered thereby.

2. An engine comprising a casing; a pair of heads closing the ends of said casing; a shaft extending through said casing; a series of pairs of blades pivotally connected at one side edge of each to the interior of said casing; the opposite side edges of the blades of each pair overlapping one another; a link-plate joining the overlapping edges of said blades and the other side edges of said blades being in contact with said heads; an intermediary between the said shaft and each pair of blades, and an expansible-fluid supply to and exhaust from the space between each pair of blades and the portion of the casing covered thereby, substantially as described.

3. An engine comprising a casing; a pair of heads closing the ends of said casing; a shaft extending through said casing; a series of pairs of blades pivotally connected at one side edge of each to the interior of said casing, the opposite side edges of the blades of each pair overlapping one another and the other side edges of said blades being in contact with said heads; the blades adjacent to the shaft being each provided with an anti-friction-roller; a cam rigidly upon the shaft upon which each of said anti-friction-roller bears, and an expansible-fluid supply to and exhaust from the space between each pair of blades and the portion of the casing covered thereby, substantially as described.

4. An engine comprising a casing; a pair of heads closing the ends of said casing; a shaft extending through said casing; a series of pairs of blades pivotally connected at one side edge of each to the interior of said casing, the opposite side edges of the blades of each pair overlapping one another and being connected together by a link-plate, and the side edges of said blades being in contact with said heads; the blades adjacent to the shaft being each provided with an anti-friction-roller; a cam rigidly upon the shaft upon which each of said anti-friction-roller bears, and an expansible-fluid supply to and exhaust from the space between each pair of blades and the portion of the casing covered thereby, substantially as described.

5. An engine comprising a casing of interior hexagonal form and recessed at its alternate angles and a pair of heads closing the ends of said casing; a shaft extending through said casing; a series of pairs of blades pivotally connected at one side edge of each to the interior of said casing at the other angles, the opposite side edges of the blades of each pair overlapping one another and being connected together by a link-plate, and the other side edges of said blades being in contact with said heads, the blades adjacent to the shaft being each provided with an anti-friction-roller; a cam rigidly upon the shaft upon which each of said anti-friction-roller bears, and an expansible-fluid supply to and exhaust from the space between each pair of blades and the portion of the casing covered thereby, substantially as described.

696,769. SULKY FLOW. HENRY SUMMERS, Canton, Mass. Filed June 28, 1904. Serial No. 64,302. (No model.)

Claim.—In a wheeled plow, a frame, a cranked shaft mounted near the front end thereof, a plow-beam having a depending shoulder at its front end and connected to said cranked shaft, a cross-bar forming a part of the frame, beneath the front end of the plow-beam, and a hand-lever fulcrumed in the frame and connected pivotally to the plow-beam, for raising and lowering the same, said shoulder being in contact with the front edge of said cross-bar when the plow-beam is in fully-lowered position, substantially as described.

696,770. STEAM-BOILER. ALEXANDER SPINER, London, Eng.
Inventor. Filed July 18, 1901. Serial No. 98,738. (No model.)

Claim.—1. In a steam-boiler, the combination of an upper steam and water vessel having a stepped lower side, an upwardly-extending water-box having a stepped inner side, and water-tubes connecting the stepped sides of said vessel and box.

2. In a steam-boiler, the combination of an upper steam and water vessel having a stepped lower side, an upwardly-extending water-box having a stepped inner side, and inclined groups of straight water-tubes connected to the stepped sides of said vessel and box.

3. A steam-boiler comprising an upper steam and water vessel having a stepped lower side, an upwardly-extending water-box having a stepped inner side, a combustion-chamber communicating with a gas-exit passage between said vessel and box, and water-tubes arranged at one side of and above said combustion-chamber and connected to the stepped sides of said vessel and box.

4. A steam-boiler comprising an upper steam and water vessel having a stepped lower side, an upwardly-extending water-box having a stepped inner side, a combustion-chamber communicating with a gas-exit passage between said vessel and box, and a number of groups of straight water-tubes of different lengths arranged in an inclined position at one side of and above said combustion-chamber and connected to the stepped sides of said vessel and box.

5. A steam-boiler comprising an upper steam and water vessel having a stepped lower side, an upwardly-extending water-box having a stepped inner side, a combustion-chamber communicating with a gas-exit passage between said vessel and box and provided near its top with a normally closed fuel-filling opening, and a number of groups of water-tubes of different lengths arranged in an inclined position at one side of and above said combustion-chamber and connected to the stepped sides of said vessel and box.

6. A steam-boiler comprising an upper steam and water vessel having a stepped lower side, an upwardly-extending water-box in communication with said vessel and having a stepped inner side, a combustion-chamber communicating with a gas-exit passage between said vessel and box and provided at its opposite side with a fuel-filling chute extending downward from its upper part, and a number of groups of straight water-tubes spaced apart in an inclined position at one side of and above said combustion-chamber and connected to the stepped sides of said vessel and box, substantially as described.

7. In a steam-boiler, the combination of an upper steam and water vessel having a stepped lower side, a readily-removable cover, and stays between said stepped lower side and cover, an upwardly-extending water-box in communication with said vessel and having a stepped inner side and a readily-removable cover having outwardly curved or convex portions and flat intermediate portions secured to the adjacent stepped inner side of the box, and a number of groups of water-tubes connected to the stepped sides of said vessel and box.

8. In a boiler, the combination of an upper steam and water vessel comprising a lower part having a stepped lower side and an upwardly-extending flanged rim arranged to form two channels along two opposite sides of the stepped portion, an inverted-dish-shaped cover adapted to be secured to the flanged rim of the lower part of the vessel, and stays connecting said lower stepped part and cover, an upwardly-extending water-box comprising an inner part having a stepped inner side and flanged rim arranged to form two upwardly-extending channels that are located at the two opposite sides of the stepped portion and are in communication at the top with the two channels in the lower part of said steam and water vessel, and an outer removable cover secured to the flanged rim of the inner part, and water-tubes connected to the stepped sides of said vessel and box, substantially as described.

9. A steam-boiler comprising a casing having vertical side walls and a rear wall provided with a fuel-filling opening near the top, said walls being arranged to form a combustion-chamber, an upper steam and water vessel having a laterally-flanged stepped lower side secured to the upper ends of the said vertical side walls, an upwardly-extending water-box having a laterally-flanged stepped inner side secured to the front ends of said side walls, and a flanged upper end connected to said vessel and formed with a gas-exit opening, groups of water-tubes connected to the stepped sides of said vessel and box, and a fire-grate at the bottom of said combustion-chamber and below said water-tubes, substantially as described.

10. A steam-boiler comprising a combustion-chamber the rear wall of which is provided with an inclined fuel-filling chute and cover, an upper steam and water vessel having a flanged lower side secured to the top of the side walls of said combustion-chamber, a vertical water-box having a flanged inner stepped side secured to the front ends of said side walls and an upper flanged part connected to the front end of said water-vessel and formed with a gas-exit opening, a fire-grate and fire-box at the bottom of said combustion-chamber, a chimney having its lower end secured over said gas-exit opening, and inclined groups of straight water-tubes connected to the stepped sides of said vessel and box, substantially as described.

11. A steam-boiler having a horizontally-arranged steam and water vessel at its upper end, a vertical water-box at its front end, and a covered inclined fuel-filling chute extending downward from near the top

of its rear end, groups of water-tubes connecting said vessel and box within the combustion-chamber of said boiler and above the fire-box thereof, an upper gas-exit passage in the angle between said vessel and box, and a chimney having its base secured over said gas-exit opening.

12. A steam-boiler having a horizontally-arranged steam and water vessel at its upper end, a vertical water-box at its front end, a covered inclined fuel-feeding chute extending downward from near the top of its rear end, and a fire-grate and ash-pan at its lower end, a fire-box arranged above said fire-grate and formed of refractory material with one or more openings with doors in its sides, inclined groups of water-tubes connecting the lower side of said vessel to the inner side of said box, an upper gas-exit opening located between said vessel and box, and a chimney having its base secured over said opening.

696,771. RUBBER TIRE FOR VEHICLE-WHEELS. JOHN M. SWERT, Batavia, N. Y., assignor of one-half to Frank Richardson, Batavia, N. Y. Filed Jan. 15, 1902. Serial No. 89,921. (No model.)

Claim.—1. An elastic tire for vehicle-wheels formed with an open longitudinal groove extending into the tire from the inner or bottom face thereof, holding devices secured to the tire and bridging said groove, and a retaining-wire or the like detachably seated in said groove and held therein by said holding devices, substantially as set forth.

2. The combination with a channel-rim, of an elastic tire arranged in said rim and provided with an open longitudinal groove which extends into the base portion of the tire from the inner or bottom face thereof, a retaining-wire or the like located in said groove, and holding devices secured to the tire and holding said retaining-wire or the like in said groove, substantially as set forth.

3. The combination with a channel-rim, of an elastic tire arranged in said rim and provided with an open longitudinal groove which extends into the base portion of the tire from the inner or bottom face thereof, a reinforcing-covering which is secured to said tire and which reinforces the walls of said groove, a retaining-wire or the like located in said groove beneath or outside of said reinforcing-covering, and holding devices secured to said tire and extending into said groove for holding the retaining-wire or the like therein, substantially as set forth.

4. The combination with a channel-rim, of an elastic tire arranged in said rim and provided with an open longitudinal groove extending into the base portion of the tire from the inner or bottom face thereof, a retaining-wire or the like located in said groove, and holding devices which are secured to the tire and span said groove, forming eyes or holes through which said retaining-wire or the like passes, substantially as set forth.

5. The combination with a channel-rim, of an elastic tire arranged in said rim and provided with an open longitudinal groove extending into the base portion of the tire from the inner or bottom face thereof, a retaining-wire or the like located in said groove, and holding devices secured to the tire, each in the form of a loop having one part thereof spanning said groove and forming therewith an eye or hole, substantially as set forth.

696,772. DENTAL CROWN-SLITTING TOOL. GEORGE W. TURNER, Philadelphia, Pa. Filed Nov. 25, 1901. Serial No. 83,498. (No model.)

Claim.—1. In a dental tool for slitting cap-crowns, a slitting-jaw comprising an arm, the free end of which is enlarged into a ring, a stud having an inner face resting upon the outer face of said ring, a stem projecting from the stud and entering the center of the ring to form a swivel connection between the stud and ring and a knife projecting radially from the periphery of the stud and having its point projecting beyond the periphery of the ring, and a bearing-jaw cooperating with the slitting-jaw.

2. In a dental tool for slitting cap-crowns, a bearing-jaw comprising an arm, the free end of which is enlarged into a cup, said cup having its rim ridged to form an annular groove concentric with the interior of the cup, in combination with a slitting-jaw comprising an arm having its free end enlarged into a ring of a diameter less than the diameter of the cup, a stud having an inner face resting upon the outer face of the ring, a stem projecting from the stud and fitting the center of the ring to form a swivel connection between the stud and ring, and a knife projecting radially from

the periphery of the stud and having a point projecting beyond the periphery of the ring and in alignment with the inner ridge of the cup in the bearing-jaw.

696,773. HEATER. WILLIAM M. THOMAS and LEBERT VAN SCOYER, Louisville, Mo. Filed Oct. 7, 1901. Serial No. 77,902. (No model.)

Claim.—1. A heater, comprising an outer drum, a fire-pot supported within the drum, an inner drum supported on the fire-pot, a drum or cylinder supported in said inner drum and having tube communications with the outer drum, and a pipe leading from the first-named inner drum and discharging underneath the fire-pot, substantially as specified.

2. A heater, comprising an outer drum, a fire-pot arranged therein, an inner drum supported on the fire-pot, a pipe leading from the upper portion of said inner drum to the under side of the fire-pot, a jacket, a smoke-pipe surrounding the jacket and communicating with the interior of the said inner drum at its lower portion, and tube communications between said jacket and the outer drum, substantially as specified.

3. A heater, comprising an outer drum, a cylinder extended upward from the bottom thereof, a fire-pot arranged in said cylinder, a drum supported on the fire-pot, a pipe leading from said drum into said cylinder and below the fire-pot, a damper or valve in the lower portion of said pipe, and a plurality of dampers in the lower portion of the outer drum substantially as specified.

4. A heater, comprising an outer drum, a fire-pot arranged in the outer drum, an inner drum, a chute leading through the wall of the outer drum and into the inner drum, a swinging trap at the inner end of said chute, a cylinder arranged within said inner drum and having communication with the space between the inner and outer drums, a pipe leading from the upper end of the inner drum to the lower portion of the fire-pot, a jacket, a smoke-pipe surrounding the jacket, and tubes leading from said jacket through the wall of the smoke-pipe, substantially as specified.

696,774. DENTAL ARTICULATOR. JOHN TIFFIN and CHARLES E. BENTLEY, Pinos Altos, N. Mex. Filed Aug. 7, 1901. Serial No. 71,168. (No model.)

Claim.—1. In a device of the class described, the combination with an upper articulating-plate, of a lower articulating-plate, each provided with antifriction devices by which the same may be moved freely against the other, and means for rigidly securing the same together against movement, substantially as shown and described.

2. In a device of the class described, the combination one with the other, of two articulating-plates adapted to receive charges of modeling-wax, handle portions extending therefrom, a stud, 14, having a screw-threaded hole carried by one handle, a slot in the other handle, support-

ing-studs on the handle and on the plate substantially at the height of the central stud, and a thumb-screw adapted to coast with the screw-thread of the stud for securing the parts together, substantially as shown and described.

3. In a device of the class described, the combination with two articulating-plates adapted to receive charges of modeling-wax, of handle portions projecting therefrom one of which is provided with a centrally-located stud having an axial screw-threaded hole, a ball-caster stud carried by one handle at the end thereof, one or more ball-caster studs carried by the other articulating-plate the handle of which is provided with a slot, and a securing-screw passing through the slot and into the axial screw-threaded hole of the stud, substantially as shown and described.

4. In a device of the class described, the combination with two articulating-plates adapted to receive charges of modeling-wax, of handle portions projecting therefrom, one of which is provided with a slot and with an antifriction-caster, and the other with an antifriction center or casters, and with a stud having a central axial screw-threaded hole for the securing-screw passing through the slot of the handle of one plate into the axial screw-threaded hole of the other so as to screw the same together, an indicating hand or pointer carried by the screw, and means adjacent to the screw adapted to receive ink or pencil marks, substantially as shown and described.

5. In a device of the class described, the combination with the upper and lower articulating-plates each of which is provided with a handle portion, of a securing-screw adjustably securing the handle portions together, means for securing an indicating-card to one of the handle portions, and a pointer connected with the device adjacent to the slot the point of which is adapted to move over the indicating-card when the plates are moved over one another, substantially as shown and described.

696,775. ELECTRIC-LIGHT SIGN. HERMAN TRIPP and GEORGE E. STEPHENSON, Chicago, Ill. Filed Dec. 17, 1901. Serial No. 86,346. (No model.)

Claim.—1. In an electric-light sign, the combination of two companion hollow bars or hangers, each bar or hanger consisting of two trough-shaped halves or sections spaced apart to leave on each side an opening or slot longitudinally of the bar or hanger, clamps or clamps encircling the body of each bar or hanger, connecting-straps or tie-bars between the two bars or hangers, and interior supporting plates or blocks for each bar or hanger, substantially as described.

2. In an electric-light sign, the combination of two companion hollow bars or hangers, each bar or hanger consisting of two trough-shaped hollow sections spaced apart to leave on each side an opening or slot longitudinally of the bar or hanger, clamps or clamps encircling the body of each bar or hanger, connecting-straps or tie-bars between the two bars or hangers, interior supporting plates or blocks of insulating material, and a conductor for each bar or hanger suspended by the interior plates or blocks, substantially as described.

3. In an electric-light sign, the combination of two companion hollow bars or hangers, each bar or hanger consisting of two trough-shaped halves or sections spaced apart to leave on each side an opening or slot longitudinally of the bar or hanger, clamps or clamps encircling the body of each bar or hanger, connecting-straps or tie-bars extending from clamp to clamp between the two bars or hangers and united at the ends to the clamps, interior supporting plates or blocks of insulating material in line with the clamps or clamps on each bar or hanger, and a conductor for each bar or hanger suspended by the plates or blocks centrally within and longitudinally of each bar or hanger, substantially as described.

4. In an electric-light sign, the combination of two companion hollow bars or hangers, each bar or hanger formed of sheet material and consisting of two trough-shaped halves or sections spaced apart to leave on each side an opening or slot longitudinally of the bar or hanger, each half

or section having three sides, clamps or clamps encircling the body of each bar or hanger, connecting-straps or tie-bars between and attached to the clamps or clamps and uniting the two bars or hangers, interior supporting plates or blocks for each bar or hanger, and a conductor suspended by the plates or blocks centrally and longitudinally of each bar or hanger, substantially as described.

5. In an electric-light sign, the combination of two companion hollow bars or hangers, each bar or hanger formed of sheet material and each consisting of two trough-shaped halves or sections having three sides and spaced apart to leave on each side of the bar or hanger as a whole an opening or slot longitudinally of the bar or hanger, clamps or clamps encircling the body of each bar or hanger, each clamp or clamp consisting of two halves or sections each half or section having four sides and each half or section having at its ends an ear, connecting-straps or tie-bars entered between the ears of the clamps or clamps, and attached to the ears by tightening-bolts and uniting the two bars or hangers, interior supporting plates or blocks having eight sides fitting the hollow trough sections or halves, and a conductor for each bar or hanger centrally and longitudinally suspended therein by the plates or blocks, substantially as described.

6. In an electric-light sign, the combination of two companion bars or hangers, each bar or hanger formed of sheet material and each consisting of two trough-shaped halves or sections, each half or section having a straight wall and a diagonal wall on each side of the straight wall, and the two halves or sections spaced apart to leave on each side of the bar or hanger as a whole an opening or slot longitudinally of the bar or hanger, clamps or clamps encircling the body of each bar or hanger, each clamp or clamp consisting of two halves or sections each half or section having a straight side, a diagonal side at each end of the straight side and a short straight end at the terminus of the diagonal sides with ears projecting at right angles from the straight ends, connecting-straps or tie-bars entered between the ears of the clamps or clamps on one side and attached to the ears by tightening-bolts and uniting the two bars or hangers, interior supporting plates or blocks, each plate or block having eight sides, three of the sides fitting the straight and diagonal walls of the hollow trough sections or halves of the bar or hanger, and a conductor for each bar or hanger centrally and longitudinally suspended by the plates or blocks in the bar or hanger, substantially as described.

7. In an electric-light sign, the combination of two companion bars or hangers, each bar or hanger formed of sheet material and each consisting of two trough-shaped halves or sections, each half or section having a straight wall and a diagonal wall on each side of the straight wall, and the two halves or sections spaced apart to leave on each side of the bar or hanger as a whole an opening or slot longitudinally of the bar or hanger, clamps or clamps encircling the body of each bar or hanger, each clamp or clamp consisting of two halves or sections each half or section having a straight side, a diagonal side at each end of the straight side and a short straight end at the terminus of the diagonal sides with ears projecting at right angles from the straight ends, connecting-straps or tie-bars entered between the ears of the clamps or clamps on one side and attached to the ears by tightening-bolts and uniting the two bars or hangers, interior supporting plates or blocks, each plate or block having eight sides three of the sides fitting the straight and diagonal walls of the hollow trough sections or halves of the bar or hanger, a conductor for each bar or hanger centrally and longitudinally suspended by the plates or blocks in the bar or hanger, and a letter detachably connected to and carried by the conductor and the bars or hangers, substantially as described.

8. In an electric-light sign, the combination of two companion hollow bars or hangers, each bar or hanger consisting of two trough-shaped halves or sections spaced apart to leave on each side an opening or slot longitudinally of the bar or hanger, clamps or clamps encircling the body of each bar or hanger, connecting-straps or tie-bars between the two bars or hangers, each connecting-strap or tie-bar connected with a clamp or clamp on each hollow bar or hanger, interior supporting plates or blocks for each bar or hanger, carrying the conductor within the bar or hanger, and openings in the bottom of each lower trough-shaped half or section of each bar or hanger, substantially as described.

696,776. LIQUID DOOR-CHECK. HENRY S. VANDY, New Britain, Conn., assignor to the Russell & Erwin Manufacturing Company, New Britain, Conn. Filed Jan. 26, 1900. Serial No. 2,173. (No model.)

Claim.—1. In a liquid door-check, the combination of a piston and cylinder counterbored at one end, with a thin supplemental cylinder having one open and one solid end and with its sides fitted closely within the supporting counterbored portion of the said cylinder and with the edge of the metal at its open end abutting the shoulder formed by the said counterbore, and a cap for closing the counterbored end of the said cylinder and pressing against the solid end of the supplemental cylinder for holding it in place, whereby the said capped end of the cylinder is provided with a lining to prevent the seam thereof from leaking under the pressure of the piston, substantially as described.

2. In a liquid door-check, the combination of a cylinder having an open end, with a cap for closing the said end, a thin supplemental cylinder of the same form as the surrounding inner wall of the main cylinder and closely fitting the same to form a lining therefor, the surrounding wall of the main cylinder serving as a support for the said lining under pressure and a piston fitted within the said lining, substantially as described.

696,777. BALL-BEARING. BALDWIN D. WARR, Milport, N. Y.
Filed Jan. 22, 1901. Serial No. 44,253. (No model.)

Claim.—In a shaft-bearing, the combination, with a cylindrical casing having internally-screw-threaded end portions, an oil-chamber at its middle part, and a base-flange upon one side; of adjustable cylinders having screw-threaded portions at one end which engage freely with the screw-threaded portions of the casing, plain cylindrical guide portions at the other end which work oil-tight in the said oil-chamber of the casing, and internal inclined bearing-surfaces; locking devices for securing the said cylinders in the casing, a shaft provided with a sleeve having ball-races at its end portions and arranged in the oil-chamber of the casing between the inclined bearing-surfaces, and balls arranged between the said inclined bearing-surfaces and ball-races, substantially as set forth.

696,778. MACHINE FOR MAKING ICE-CREAM SANDWICHES.
LOREN WHEELER, JR., Philadelphia, Pa. Filed June 24, 1901. Serial No. 65,885. (No model.)

Claim.—1. The combination of the hollow standard, provided with a socket; the box at the end of the standard; a false bottom in the box; a spindle movable in said socket and connected to the false bottom; a guide-sleeve in the walls of the standard and having a side offset, and a pin connected to the standard and movable in said sleeve, the length of the sleeve being sufficient with reference to the position of the pin, to allow the false bottom to be lifted entirely out of the box; substantially as described.

2. The combination of the hollow standard, provided with a socket; the box at the end of the standard; a false bottom in the box; a spindle movable in said socket, and connected with the false bottom; a guide-sleeve in the walls of the standard; a pin attached to said spindle and an offset at the side of said guide-sleeve, the portion of the bottom walls of which away from the guide-sleeve being higher than the portion nearest the guide-sleeve; substantially as described.

3. In an ice-cream-sandwich machine, the combination with the box having a vertically-movable false bottom, of a screw penetrating a wall of said box and being movable in and out of the line of motion of said false bottom; substantially as described.

4. In an ice-cream-sandwich machine, the combination of the vertical standard; the box supported on the standard; the socket in the standard; the vertically-movable false bottom of said box; the spindle moving in said socket connected to said false bottom; and the raised dam around the top of said socket; substantially as described.

696,779. STOCKING GUARD. HENRY WHEAT, New York, N. Y.
Filed Feb. 3, 1901. Serial No. 44,096. (No model.)

Claim.—1. As a new article of manufacture, a stocking-guard, comprising a frame consisting of two bows of unequal length and having the ends of their members pivoted together, the bows being adapted to engage over the leg of the wearer, one above and the other below the knee, and a flexible material secured to the bows and extending between them, as set forth.

2. As a new article of manufacture, a stocking-guard, consisting of two bows having the ends of their members pivoted together, the bows being of unequal length and adapted to engage over the leg of the wearer, the longer one above and the shorter one below the knee, a flexible material secured to the bows and extending between them, and fastening straps secured to the guard at joint of the bows, as set forth.

696,780. FIRE-EXTINGUISHER. MARTIN E. WILLER, Fort Plain, N. Y., assignor of two-fifths to Alphonse Wehrath, Fort Plain, N. Y. Filed Jan. 10, 1901. Serial No. 42,792. (No model.)

Claim.—1. In a fire-extinguisher, the combination with a liquid-holding tank and a removable cap or cover therefor, of a cage-like structure secured to said cap or cover and adapted to receive and support an acid-bottle, and a diving-bell air-check sealing device for said bottle arranged and adapted to slide within said cage-like structure, said acid-bottle and its sealing device being adapted to be submerged within and below the surface of the liquid in said tank; substantially as described.

2. In a fire-extinguisher, the combination with a liquid-holding tank and a removable cap or cover therefor, of a cage-like structure secured to said cap or cover and adapted to receive and support an acid-bottle, a side opening in said cage-like structure and a reversible door therefor, and a diving-bell air-check sealing device for said bottle arranged and adapted to slide within said cage-like structure, said acid-bottle and its sealing device being adapted to be submerged within and below the surface of the liquid in said tank; substantially as described.

3. In a fire-extinguisher, the combination with a liquid-holding tank and a removable cap or cover therefor, of a cage-like structure comprising a series of wires or rods secured to said cap or cover and extending within the tank, near the bottom thereof and provided with a bottom, as

acid-bottle arranged within said cage-like structure and adapted to be supported upon the bottom thereof, and a diving-bell air-check sealing device for said bottle arranged and adapted to slide within said cage-like structure, substantially as described.

4. In a fire-extinguisher, the combination with a liquid-holding tank and a removable cap or cover thereof, of a cage-like structure comprising a series of wires or rods secured to said cap or cover and extending within the tank near the bottom thereof and provided with a bottom, a side opening in said cage-like structure, a revolving door for said opening comprising two rings connected by wires and supported upon said cage-like structure, an acid-bottle arranged within said cage-like structure upon the bottom thereof, stops for confining said revolving door and acid-bottle in place, and a diving-bell air-check sealing device for said bottle arranged and adapted to slide within said cage-like structure, substantially as described.

5. In a fire-extinguisher, the combination with a liquid-holding tank and a removable cap or cover thereof, of a cage-like structure comprising a series of wires or rods secured to said cap or cover and extending within the tank to near the bottom thereof and connected with a bottom piece, one of said wires being cut away to form a side opening for the entrance of an acid-bottle, and a revolving door for said side opening, comprising rings surrounding said cage-like structure and connected by wires, one of said wires being bent inwardly to extend substantially in line with the cut-away wire of the cage-like structure to thereby center and confine the acid-bottle in place, substantially as described.

6. In a fire-extinguisher, the combination with a liquid-holding tank, of a cage-like structure adapted to support and confine an acid-bottle near the bottom of said tank, and a weighted sealing device for said bottle comprising an inverted-cup-like device arranged and adapted to slide within said cage-like structure, and an acid-proof packing arranged in the recess of said cup-like device and adapted to engage the mouth of the bottle, the wall of said cup-like device extending below the mouth of said bottle, whereby when said acid-bottle and its sealing device are submerged in the liquid in the tank, air will be confined within said sealing device about the mouth of the bottle, substantially as described.

696,781. TROLLEY CATCHER AND RETRIEVER. CHARLES F. WILSON, Brooklyn, N. Y. Filed Aug. 12, 1891. Serial No. 71,808. (No model.)

Claim.—1. In a device of the character herein set forth, the combination with a spool carrying dogs, of an outer casing arranged to turn with respect to the back-plate, the same being supplied with an operating-spring and calculated to wind the trolley-rope upon its exterior, substantially as and for the purpose set forth.

2. In combination with the revolving drum and its operating-spring, a dog for holding said drum against the action of the spring, and means substantially as described for releasing said dog by turning the drum against the action of the spring, substantially in the manner and for the purpose set forth.

3. In a device of the character herein set forth, the combination of a spool carrying dogs, a revolving casing or drum outside said spool, and a stationary back, the spool and drum being mounted upon and arranged to turn upon the same axis, substantially as shown and for the purpose set forth.

4. In a device of the character herein set forth, the combination with the spring-actuated exterior drum and the stationary back, of a dog for holding said drum against the action of its actuating-spring, said dog be-

ing supported upon the back and held normally free from engagement with the drum, substantially in the manner and for the purpose set forth.

5. In a device of the character herein set forth, the combination of the spool, the dogs carried by said spool, a revolving casing for the spool, a stationary back, and a dog for engagement with the drum, the drum being actuated by a spring and being mounted upon the same axis as the inner spool, substantially as shown and described.

696,782. DRIVING-GEAR. JOHN C. WOOST, Mount Vernon, Ind., WILLIAM R. BAILEY, Denver, and WILLIAM H. YOUNG, Rockyford, Colo. Filed July 10, 1901. Serial No. 67,796. (No model.)

Claim.—1. A driving-gear, comprising a frame arranged to support the machine to be driven, a crank-shaft having crank-arms provided with pedals, bearings for the crank-shaft adjustable on the frame, a sprocket-chain and sprocket-wheel connection between the crank-shaft and the main shaft of the machine to be driven, the sprocket-wheel being arranged centrally between the bearings, a seat on the said frame, a brace connected with the frame below the seat and adapted to engage the machine to be driven, the brace being adjustable in length to suit the machine to be operated, and to brace the same against strain from the chain, said a handle-bar on the said adjustable brace, as set forth.

2. A driving-gear, comprising a frame having longitudinal spaced bars, a platform at the front end of the bars for supporting the machine to be driven, a crank-shaft having crank-arms provided with pedals, a sprocket-chain and sprocket-wheel connection between the said crank-shaft and the main shaft of the machine to be driven, a standard at the rear end of the bars, a seat carried by the said standard, a handle-bar on the frame, the bearings of the crank-shaft being mounted to slide longitudinally on the spaced bars in front of the standard; and means for adjusting the bearings, as set forth.

3. A frame for a driving-gear, comprising longitudinal spaced bars, a platform on the front end of the bars, legs for supporting the front ends of the bars and platform, a standard at the rear end of the bars, bearings on the said platform for supporting the machine to be driven, an upper brace connecting the bearings with the standard, the said upper brace being adjustable in length to compensate for changes in the position of the bearings and a center brace connecting the standard with the said bars, as set forth.

4. A frame for a driving-gear, comprising longitudinal spaced bars, a platform on the front end of the bars, legs for supporting the front ends of the bars and platform, a standard at the rear end of the bars, a bearing adapted to be secured on the said platform for supporting the machine to be driven, an upper brace adapted to connect the standard with the said bearing, the brace being made in sections and adjustable in suit the position of the machine to be operated, a center brace connecting the

standard with the said bars, and a set of adjustable legs on the said bars below the point of connection of the center brace with said bars, as set forth.

5. A frame for a driving-gear, comprising longitudinal spaced bars, a platform on the front ends of the bars, legs for supporting the front ends of the bars and the platform, a standard at the rear ends of the bars, bearings on the said platform for supporting the machine to be driven, an upper brace connecting the bearings with the standard, the brace being made in telescopic sections fastened together whereby it may be adjusted to suit changes in the position of the bearings on the platform, and a center brace connecting the standard with the said bars.

696,783. WINDOW-SCREEN. HENRY T. WISNET, Philadelphia, Pa. Filed July 6, 1901. Serial No. 67,342. (No model.)

Claim.—1. In an apparatus of the character described, a window-screen, a horizontal flange formed with the upper portion of the framework of said screen, said flange adapted to come in contact with the casing, means for detachably securing said flange to the casing for the purpose of raising and lowering the screen with the casing, a recess formed in the wall in which the screen is adapted to receive the casing when the casing is closed, guide-ways formed in the upright portion of the window-casing in which the side frames of the screen are adapted to slide, said guide-ways being such as to allow the screen to be pushed a sufficient distance to one side to allow the removal of one edge of the screen for the purpose of removing the screen entirely, substantially as described and for the purpose specified.

2. In combination with an apparatus of the character described, a screen, a horizontal flange formed with the upper framework of the screen, a slot formed through said flange, spring-arms arranged within the cross-rails of the casing, beveled projecting portions formed upon the free end of the spring-arms, said spring-arms adapted to be normally in contact with one another for the purpose of inserting the same through the slot in the flange of the screen, means for spreading said spring-arms for the purpose of attaching the screen to the casing, substantially as and for the purpose set forth.

3. In combination with an apparatus of the character described, two spring-arms secured in the cross-rail of the window-casing, the free ends of said spring-arms projecting beyond the casing, outwardly-extending beveled portions formed upon the free end of said spring-arms, said spring-arms adapted to be in contact with one another when in their normal position, a slot formed within the screen-frame through which the ends of the spring-arms are adapted to protrude when the screen is brought in contact with the casing, an oblong button adapted to be pivoted between the spring-arms, said button adapted to spread the arms when turned to its greatest length in a horizontal position, a knob secured upon the outside of the casing for the purpose of turning said button, substantially as and for the purpose set forth.

696,784. MACHINE FOR MAKING METAL BINDING-STRIPS. FREDERICK W. R. YAGER, Chicago, Ill. Filed May 12, 1901. Serial No. 59,909. (No model.)

Claim.—1. In a machine of the class described the combination of the shear for cutting the strips from a sheet, adjustable stops for determining the width of the strips to be cut, a discharging device for launching the strips forward after the cutting, an intermediate stop for arresting the travel of the strip edge bringing it into alignment, stops for adjusting the position of the strips to be bent with clamping and bending devices

and means for automatically actuating the several parts, substantially as shown and described.

2. In a machine of the class described, the combination of a shear for cutting the strips, mechanism for discharging covered strip from the shear, stops for holding the covered strip in a position to be bent, and a clamping-bar and a revolving bender, substantially as shown and described.

3. In a machine of the class described, the combination with a feeding-table fixed at an angle insuring the sliding of a sheet placed thereon, of means for arresting the sliding at a certain point, shearing device arranged to cut a strip from the lower side of the arrested sheet, an inclined platen in position to receive the covered strip, means for arresting the strip after it has advanced a certain distance upon the platen, and means for bending the strip.

4. The combination of a feeding-table, of a cutting-shear, adjustable stops for regulating the width of the strips to be cut, and a strip-launching device with stops and bending devices for bending the strips, substantially as shown and described.

5. In a machine of the class described, the combination with a feeding-table, of shearing device arranged to cut a strip from a sheet upon the table, stops normally limiting the advance of such sheet and at an adjustable distance from the shearing-line, a platen in position to receive the covered strip, means for clamping the strip against the platen, a rotary bender normally lying below one side of the strip when so clamped, and automatic means for rotating the bender toward the strip through approximately one hundred and eighty degrees, to bend the strip back upon itself.

6. In a machine of the class described, the combination with a feeding-table and shearing device to cut a strip from a sheet thereon, a platen in position to receive the covered strip, strip clamping and bending devices, and stops between the shearing and clamping devices to adjust and temporarily arrest the strip.

7. In a machine of the class described, the combination with a feeding-table and shearing device for severing a strip from a sheet thereon, of stops adjustable in distance from the shearing-line, to vary the width of strips, a platen in position to receive the covered strip, an automatic stop to arrest the advancing strip when its side projects to the proper distance over the platen's edge, a clamping-plate to press the non-projecting portion of the strip against the platen, a bender normally alongside the plate of the projecting portion of said strip, and means for swinging the bender about the edge of the clamping-plate to double the strip back upon itself.

8. The combination of a feeding-table, of adjustable stops for regulating the amount of feed, a cutting-off shear for severing the strip from a sheet as held upon the feeding-table, a platen for receiving the strip from the shear, and a bending device mounted upon the platen for bending the strip after the cutting, said platen being recessed to permit the passage of the adjustable feeding-stops through the surface of the platen, substantially as shown and described.

9. In a machine of the class described, the combination with a feeding-table inclined at an angle insuring the sliding of a sheet placed thereon, of a similarly-inclined plate in position to receive a strip falling from the edge of the feeding-table, an automatic clamp for momentarily holding a sheet upon the feeding-table, automatic shearing device for severing a strip while the sheet is so held, a clamp for holding a strip against the plate, and an automatic bender arranged to fold the strip back upon itself while thus clamped.

10. In a machine of the class described, the combination with a feeding-table and shearing device near one side of the same, of steps adjustable in distance from the shearing-line, a plate slightly below, and parallel to, the strip at the instant of severing, a device for impelling the severed strip sidewise across the plate, and clamping and bending device arranged to receive the strip and bend it.

11. The combination of a feeding-table, an adjustable step for regulating the width of the feed, a shear for cutting a strip from the sheet as held upon the table, a launching device for discharging the strip from the shear, and a plate for receiving the strip from the shear and clamping and bending device mounted upon the plate, substantially as shown and described.

696,785. TOOTHPIKE-HOLDER. GREGG A. YARRI, Havana, Cuba. Filed Aug. 2, 1901. Serial No. 79,030. (No model.)

Claim.—1. A holder for toothpicks, comprising a casing having a conical end provided with an opening at its apex, a shoulder at the junction of said conical end and the body portion of the holder, and a retaining-plate for engaging against said shoulder, the said retaining-plate having openings around its edge, substantially as specified.

2. A holder for toothpicks, comprising a casing having a conical end provided with an opening through which a pick may pass, the said end normally forming the top of the casing, a retaining-plate arranged at the base of said conical end and having openings around its edge, the center being imperforate, and a removable bottom for the casing, substantially as specified.

696,786. MECHANISM FOR CONVERTING MOTION. GEORGE W. ELLIFF, Elyria, Minn. Filed Jan. 13, 1902. Serial No. 80,794. (No model.)

Claim.—1. In a device for converting motion, the combination of a lever having extensions on each side of its fulcrum, links pivoted to the extensions of the lever, jointed pawls pivoted to the links, a support to which one end of the jointed pawls are pivoted, and a ratchet-disk rotatably supported to be engaged by the free ends of the pawls, substantially as shown.

2. In a device for converting motion, the combination with a T-headed lever fulcrumed between its heads, a link connected to each end of the head of the lever, arms pivoted upon a support said arms being of

different lengths, pawls connected to the arms and to the links, a ratchet-wheel with which the ends of the pawls engage and springs for holding the pawls in engagement with the ratchet-wheel, substantially as shown and for the purpose set forth.

3. In a device for converting an oscillating motion into a reciprocating one, a T-headed lever fulcrumed upon a support, arms pivoted so as to be maintained in line with each other upon the support, one of the arms being longer than the other, pawls of different lengths pivoted to the arms, a ratchet-wheel with which the pawls engage, and links connecting the arms and pawls to the lever so that the joints between the pawls and arms will be alternately raised and lowered, substantially as set forth.

696,787. APPARATUS FOR FEEDING AND TEMPERING FOUNDRY-SAND. ALFRED M. ACKER, Pittsburg, Pa. Filed Oct. 28, 1901. Serial No. 79,004. (No model.)

Claim.—1. In a device for feeding and tempering foundry-sand, &c., the combination with a receptacle or hopper, of a feeder-pan under said hopper, a feeder-bar within said feeder-pan, means engaging with said feeder-pan to lower and raise the same, a reciprocating bar having projections thereon engaging with recesses in the feeder-bar to move the same and discharge the material from said pan, and means for reciprocating said bar.

2. In a device for feeding and tempering foundry-sand, &c., the combination with a receptacle or hopper, of a feeder-pan under said hopper, a feeder-bar within said feeder-pan, a fulcrumed lever pivoted to said pan and provided with a weight thereon to raise the pan, a reciprocating bar adapted to engage with the feeder-bar to move the same and discharge the material from said pan, and means for reciprocating said bar.

3. In a device for feeding and tempering foundry-sand, &c., the combination with a receptacle or hopper, of a feeder-pan under said hopper, a feeder-bar within said feeder-pan, a fulcrumed lever pivoted to said pan and provided with a weight thereon to raise the pan, a reciprocating bar having projections thereon engaging with recesses in the feeder-bar to move the same and discharge the material from said pan, and means for reciprocating said bar.

4. In a device for feeding and tempering foundry-sand, &c., the combination with a receptacle or hopper, of a feeder-pan under said hopper, a feeder-bar within said feeder-pan, means for lowering and raising said feeder-pan, a reciprocating bar adapted to engage with the feeder-bar to move the same and discharge the material from said pan, means for reciprocating said bar, and means for supplying water to said material.

5. In a device for feeding and tempering foundry-sand, &c., the combination with a receptacle or hopper, of a feeder-pan under said hopper, a feeder-bar within said feeder-pan, means for lowering and raising said feeder-pan, a reciprocating bar adapted to engage with the feeder-bar to move the same and discharge the material from said pan, means for reciprocating said bar, and a pipe connected to a water source and adapted to supply water to the material.

6. In a device for feeding and tempering foundry-sand, &c., the combination with a receptacle or hopper, of a feeder-pan under said hopper, a feeder-bar within said feeder-pan, means for lowering and raising said feeder-pan, a reciprocating bar adapted to engage with the feeder-bar to move the same and discharge the material from said pan, means for reciprocating said bar, a pipe connected to a water source and provided with a valve therein, and connections between said pan and valve for opening and closing said valve to supply water to the material.

7. In a device for feeding and tempering foundry-sand, &c., the combination with a receptacle or hopper, of a feeder-pan under said hopper, a feeder-bar within said feeder-pan, means for lowering and raising said feeder-pan, a reciprocating bar adapted to engage with the feeder-bar to move the same and discharge the material from said pan, means for reciprocating said bar, a pipe connected to a water source and provided with a valve therein, a lever on said valve, and a bar or chain connected to said pan and lever for opening and closing said valve to supply water to the material.

696,788. OPTICAL OBJECTIVE. CHAS. C. ALLEN, Chicago, Ill. Filed Feb. 26, 1901. Serial No. 44,798. (No model.)

Claim.—An optical objective consisting of two fixed outer lens elements, a movable intermediate lens element adapted to be adjusted in varying intermediate positions between the two outer lens elements, and means for adjusting the intermediate lens element, substantially as described.

696,789. AUTOMATIC REGULATING DEVICE FOR STEAM-HEATERS. EDWARD R. ALLEN and WILLIAM R. SALMON, Flemington, N. J., assignors to the Allen and Van Nest Company, Flemington, N. J., and New York, N. Y. Filed Feb. 11, 1901. Serial No. 46,838. (No model.)

Claim.—1. The combination with a steam-generator provided with a draft-damper, a fine-damper and a check-draft, of regulating devices including a clamping-collar adapted to be secured to a pipe connected with the generator and provided with two oppositely-extending arms, an operating-lever pivoted to one of said arms, a connection providing for lost motion extending from one end of said lever to the draft-damper, a governor actuated by steam-pressure operatively connected with said lever, a second lever pivoted to the other arm of said collar having one end movably connected to said first lever and the other end connected to the fine-damper, said connections providing for lost motion and connections also providing for lost motion between said second lever and the check-draft, substantially as described.

2. The combination with a steam-generator provided with a draft-damper, a pivoted fine-damper and a check-draft damper in the smoke-pipe adjacent to the fine-damper, of regulating devices including an operating-lever, a steam-pressure governor connected therewith, a connection providing for lost motion between said lever and the draft-damper, a second pivoted lever having one end operatively connected with the first lever, an operating-arm on the pivot of the fine-damper, a connection providing for lost motion extending from said arm to the fine end of said second lever, a second arm on the pivot of the fine-damper and a part connected with the check-draft damper normally out of engagement with said second arm but adapted to be engaged thereby when the fine-damper is closed, to open the check-draft damper, substantially as described.

696,790. DINNER-PAIL. HENRY C. ASHMAN, Louisville, Ky., assignor of one-half to WILLIAM MILLER, Louisville, Ky. Filed May 28, 1901. Serial No. 61,908. (No model.)

Claim.—1. A dinner-pail comprising a base, having a support arranged thereon, said support having one or more hinged sections, and a cover adapted to be fitted over the support and to be fastened thereon, substantially as described.

2. A dinner-pail comprising a base having a support arranged thereon, said support having one or more hinged sections, and a cover fitted

over the support and adapted to be fastened to the top of said support, substantially as described.

3. A dinner-pail comprising a base, a support adapted to receive a vessel or receptacle thereon, and also having hinged sections, the top of said support having a napkin-holder arranged thereon, and a cover adapted to fit over the base and support and provided with means for attaching the top to the support, substantially as described.

4. A dinner-pail comprising a base having one or more receptacle-holders arranged thereon, a support arranged upon the base and adapted to receive and hold a vessel or receptacle, said support having hinged sections carrying holders, and a cover fitting upon the base over the support and provided with fastening means, substantially as described.

5. A dinner-pail comprising a base having holders arranged thereon, a support having hinged holders adjacent to its upper end, a napkin-holder at the top and knife, fork and spoon racks at the ends, and a cover adapted to fit over the support and rest upon the base, and means for fastening said cover, substantially as described.

6. A dinner-pail comprising a base having a central depression, said base having receptacle-holders arranged within the depression and upon opposite sides thereof, the support arranged centrally of the base and adapted to receive and hold a bottle, the hinged sections carrying holders, the egg-holders carried by the support, the knife, fork and spoon racks arranged upon the sides of the support and the napkin-holder upon the top, and the cover having a handle, said cover being adapted to fit over the support and holders and rest upon the base, and the fastening means carried by the said cover for securing the parts together, substantially as described.

696,791. HEATING-FURNACE. LYMAN S. BAKER, Canton, Mich. Filed May 11, 1901. Serial No. 58,764. (No model.)

Claim.—In a furnace for heating purposes, in combination with a rectangular fire-pot, a rectangular combustion-chamber thereabove, a heating-chamber above said combustion-chamber, and smoke-outlet pipes located above the corners of the fire-pot, extending and converging to a common center, in said heating-chamber toward the top thereof.

696,792. CURSTONE. JOHN E. BUELL, St. Louis, Mo. Filed Jan. 13, 1902. Serial No. 69,491. (No model.)

Claim.—1. A curstone, having a projection and a recess upon one end, and a corresponding projection and recess upon the opposite end;

the faces carrying the recesses extending beyond the faces carrying the projections, and there being horizontal overlapping faces between the projections and recesses substantially as specified.

2. In a curbstone, a body having projections and recesses in its end faces, the projections of one section adapted to enter the recesses of the adjacent section, the faces having the recesses extending beyond the faces having the projections, and there being overlapping faces between the projections and recesses as required to support the section and guide the projections into the recesses.

696,798. TANK-LUG. CHARLES E. BAKER, Racine, Wis. Filed Nov. 15, 1901. Serial No. 28,694. (No model.)

Claim.—1. In combination, a coupling-bolt, a flat metal band or hoop, a tank-lug having a side closed band-slot extending completely therethrough and tapered or flared from one end to the other and therefore with the large accessible opening at one edge of the lug and the small opening at the opposite edge of the lug, and a rolling key entirely within said slot and resting throughout its length against the flat inclined outer wall of the slot and across the band and readily accessible at the large open end of the slot, said lug having a transverse bolt-eye, substantially as described.

2. A tank-lug having a transversely-arranged eye for the coupling-bolt, and a tapered band-slot extending completely therethrough with the large end opening at the inner face or edge of the lug and the small end opening at the outer opposite face or edge of the lug, one wall of said slot forming a flat seat for the band, and the other wall of said slot extending from opening to opening and the full width of the slot and forming a flat seat the full length of the wedging rolling key, in combination with a rolling key insertible and accessible at the large end of the slot and throughout its length wedging between the band and opposite wall of the slot, and a coupling member, substantially as described.

3. A tank-lug having a band-slot extending completely therethrough and flared from one end to the other with the inner and outer flat walls of said slot both inclined, substantially as described, the band adapted to rest against one of said walls within said slot, said lug formed with a transverse coupling-bolt eye exterior of said slot, in combination with a rolling locking-key insertible at the large end of the slot and readily accessible through said end and located entirely within and wedging between the band and the other inclined wall, and a coupling-bolt, substantially as described.

4. In combination, in a coupling device, a band, a coupling, a lug having a band-opening, and a band-locking wedge for locking the band in the lug comprising several loosely-joined rolling keys, substantially as described.

5. A tank-lug formed in one piece of metal with a transverse coupling-bolt eye and two side walls connected by two end walls with a tapered band-slot between said walls and extending completely through the lug and having the large exposed inner end opening and the small outer end opening, the inner wall or face of the slot being inclined to cause bending of the band when locked in the slot against said face, in combination with a separate rolling locking-key insertible and accessible through said large exposed end of the slot, substantially as described.

6. A tank-lug having a coupling-bolt eye, and a tapered or flared band-slot extending completely through the lug with its large exposed end at the inner edge of the lug and its small end at the outer face of the lug, the outer face or wall of the slot being continuous and flat, in combination with an elongated rolling or rocking key located entirely within the slot and insertible and accessible through the large end of the slot and throughout its length resting against and wedging between said flat wall of the slot and the band across which it extends, the coupling-bolt, and the band, substantially as described.

7. In combination, a coupling-bolt, a flat hoop or band, a tank-lug having a bolt-eye and formed with the slot therethrough flaring from the small outer edge opening to the large inner edge opening, with the inner and outer flat walls of the slot both inclined from the small opening to the large opening to bend the band, as described, and wedge the rolling locking-key, and the removable rolling locking-key located entirely within the slot and accessible through the large opening and throughout its length bearing against one flat inclined wall and the inclined surface of the band within the slot, substantially as described.

8. In combination, in a coupling, a tank-lug having a band-slot with an inclined wall, and a separate locking-wedge adapted to wedge between a wall of said slot and a portion of the band and comprising several loosely-connected elongated rolling keys, substantially as described.

9. In combination, in a band or hoop coupling, a hoop or band, a lug having a band-locking slot extending therethrough, and a band-locking wedge comprising several keys arranged side by side, and a cage coupling the keys together, substantially as described.

10. A tank-lug-locking wedge comprising several parallel loosely-confined keys having longitudinal flattened portions and rounded gripping or engaging edges, substantially as described.

11. A tank-lug-locking wedge comprising several parallel rocking or rolling keys with notched end edges, and a cage passing around and loosely confining the keys together and fitting in said notched ends, substantially as described.

12. A tank-lug-locking wedge comprising several flattened elongated keys, one end key having its outer face longitudinally grooved, the ends of the keys having flared notches, and the binding-wire in said groove and notches, substantially as described.

13. In combination, a band, a coupling, a lug having a band-locking slot, and a band-locking key comprising several keys of differing diameters, and means confining the keys together to permit independent rocking or rolling movement, substantially as described.

14. In combination, a band, a coupling, a lug having a band-locking slot flared from end to end and having the small opening at the outer edge of the lug and the large accessible opening at the inner edge of the slot, and a removable band-to-key wedge comprising several connected elongated rolling keys located entirely within the slot and accessible through said large opening and throughout their lengths bearing against one wall of the slot and a face of said band, substantially as described.

15. In combination, a band, a coupling-bolt, a lug having a flared band-locking slot extending completely therethrough with a large readily-accessible inner end opening, and removable separate elongated rolling locking-keys located entirely within said slot and accessible through said large opening, and bearing throughout their lengths against a flat wall of the slot and a face of the band, said keys arranged end to end, substantially as described.

696,794. CUTTER-HEAD. NORMAN ELY, Crownpoint, N. Y. Filed Sept. 22, 1901. Serial No. 70,692. (No model.)

Claim.—1. A cutter-head, comprising cutter-blocks, knives on said cutter-blocks, chip-breakers carried by the cutter-blocks and having beveled outer ends to engage the bevels of the knives, a circular saw between the cutter-blocks, and a carrier for attachment to a spindle or mandrel and removably supporting the said blocks and saw, the said carrier having means for clamping the blocks and saw together and holding the same in position on the carrier, as set forth.

2. A cutter-head having cutter-bars arranged in sets, segmental knives held adjustably on the outer ends of one set of cutter-bars, straight knives held adjustably on the outer ends of the other set of cutter-bars, and a chip-breaker for each knife having a beveled edge to engage the bevel of the knife, as set forth.

3. A cutter-head, comprising a cutter-block having two sets of radial guideways, sets of cutter-bars slidably secured in the said guideways each cutter-bar having a guideway at its outer end, segmental knives adjustably secured on the guideways of one set of cutter-bars, straight knives secured on the guideways of the other set of cutter-bars, and chip-breakers secured to the cutter-bars and having their outer ends beveled, as set forth.

4. A cutter-head having a cutter-bar, a knife held on said cutter-bar, and a chip-breaker adjustably secured on the cutter-bar and having a beveled outer end to engage the bevel of the knife, as set forth.

5. A cutter-head, having a knife, and a chip-arrester and knife-outer engaging the bevel of the knife, as set forth.

6. A cutter-head, comprising a cutter-block having radial guideways, cutter-bars slidably secured in the said guideways, each cutter-bar having a peripheral guideway at its outer end and a segmental knife adjustably secured on the guideway of the said cutter-bar, and a chip-breaker adjustably secured on the side of the cutter-bar to engage the bevel of the corresponding knife, as set forth.

7. A cutter-head, comprising a cutter-block having radial guide-ways, outer-bars slidably secured in the said guide-ways, each outer-bar having a peripheral guideway at its outer end and a segmental knife adjustably secured on the guideway of the said outer-bar, and a chip-breaker adjustably secured on the side of the outer-bar to engage the bevel of the corresponding knife, the said chip-breaker having a beveled outer end for engaging the bevel of the knife, as set forth.

8. A cutter-head, comprising outer-blocks, outer-bars adjustable on the outer-blocks and formed with guide-ways, segmental and straight knives arranged alternately on said guide-ways and fitted to slide thereon, means for securing the knives in place on the outer-bars after adjustment, chip-breakers adjustably secured to the sides of the outer-bars and having their outer ends beveled to engage the bevels of the said knives, a saw between the outer-blocks and a carrier for attachment to a revoluble spindle and removably supporting the said outer-blocks and saw, as set forth.

696,795. AXIAL-FLOW TURBINE. WILK & BOK and TYGER R. ROSSMAN, Stockholm, Sweden. Filed Jan. 22, 1899. Serial No. 708,366. (No model.)

Claim.—An axial-flow turbine having a plurality of concentric circles of buckets situated in the same radial plane, and having for each circle of buckets an inlet for a fully-expanded driving fluid at one side, and a discharge-outlet for same to the exhaust on the opposite side, the inlet for one circle of buckets being situated on the same side with the outlet for another circle, whereby the same driving fluid passes but once axially through the turbine, for the purpose of absorbing and transmitting the maximum energy of the driving fluid with one turbine body, substantially as set forth.

696,796. COATING FOR NAILS. JOHN V. BRAUCH and EDWARD HERMAN, Belleville, Ill. Filed June 13, 1901. Serial No. 64,372. (No specimens.)

Claim.—A composition consisting of crude turpentine and linseed oil substantially in the proportions of forty per cent. crude turpentine and sixty per cent. linseed oil.

696,797. VAPOR-GENERATOR. MARCELIN CANTERLAS and CHARLES THIAUX, Paris, France. Filed July 30, 1901. Serial No. 70,268. (No model.)

Claim.—1. A vapor-generator, comprising a cylinder built up of separate segmental blocks of steel fitted together so as to form a hollow cylinder, each block being provided with a duct and the several ducts communicating with each other, and means for heating the interior of said cylinder.

2. A vapor-generator, comprising a cylinder built up of segmental blocks of steel fitted together so as to form a hollow cylinder, each block being provided with a duct and the several ducts communicating with each other, means for heating the interior of said cylinder, and coils of pipe communicating with said ducts and surrounding said cylinder exteriorly.

3. As an article of manufacture, an element in the construction of a generator, comprising a tubular member of steel having a general sinus form and embedded in a star-shaped block of cast-steel so as to be integral therewith.

4. As an article of manufacture, an element in the construction of a generator, comprising a tubular member of steel making a plurality of return-bends upon itself and embedded in a solid block of cast-steel so as to be integral therewith.

696,797.

696,798. BRUSH. JAMES H. CHANDLER, Thompson, Conn. Filed June 7, 1901. Serial No. 62,534. (No model.)

Claim.—1. A brush, comprising a casing, brush material carrying bars mounted to rock in said casing, shifting bars movable lengthwise in the casing, parts on the rocking bars for engaging with the shifting bars, a combined handle and cover having swinging connection with the casing, and means operated by a swinging movement of said handle and cover for moving the shifting bars in one direction, the said cover consisting of sections connected to fold one upon another, substantially as specified.

2. A brush, comprising a casing, brush-carrying bars mounted to rock in said casing, shifting bars movable lengthwise in the casing and having notches in their upper edges, projections on the rocking bars for engaging in said notches, a rod connection between the shifting bars at one end, a spring engaging with the other ends of the shifting bars, a shaft mounted at one end of the casing, concentric mounted on said shaft, an eccentric-rod extended from the eccentric to the connecting-rod of the shifting bars, a locking device for the shaft, and a combined cover and handle connected to said shaft, substantially as specified.

3. In a brush, a casing, bristle-carrying bars mounted to rock in said casing, shifting bars connecting with said rock-bars, a combined handle and cover, consisting of an inner portion and two flaps or wings hinged to the side edges thereof, and means operated by a swinging movement of the combined handle and cover for moving the shifting bars in one direction, substantially as specified.

696,799. HEAT REGULATING OR GOVERNING APPARATUS. THOMAS CLARKSON, London, England. Filed Oct. 20, 1901. Serial No. 50,221. (No model.)

Claim.—1. In apparatus for governing vapor, oil and similar burners, the combination with regulating mechanism, of a pump operating a fluid which directly actuates the regulating mechanism, a constantly-moving member yieldingly connected to the pump, a locking-arm connected to the pump, a plug on the arm, and a chamber in which the contents of the generator have access, cooperating with the plug to lock and release the arm in the manner and for the purpose set forth.

2. In apparatus for governing vapor, oil and similar burners, the combination with regulating mechanism comprising levers controlling the burner, of a pump, a constantly-moving member yieldingly connected to the pump, a locking-arm, a plug connected to the arm, and a chamber in which the contents of the generator have access and which cooperates with the plug to lock or release the arm, substantially as described.

3. In apparatus for governing vapor, oil and similar burners, the combination with lever-regulating mechanism, of a diaphragm, a diaphragm-chamber, a fluid-reservoir for the diaphragm-chamber, a pump communicating with the reservoir and with the diaphragm-chamber, a constantly-moving lever yieldingly connected with the pump, a locking-arm connected to the pump, a plug on the arm, and a chamber subjected directly to the temperature of the contents of the generator and which cooperates with the plug to lock and release the arm, substantially as described.

4. In apparatus for governing vapor, oil and similar burners, the combination with lever-regulating mechanism, of a flexible diaphragm, a diaphragm-chamber, a fluid-reservoir for the diaphragm-chamber, a pump communicating through valve-controlled conduits with the diaphragm-chamber and the reservoir, a constantly-moving lever yieldingly connected to the pump-plunger, a locking-arm connected to the pump-plunger, a plug on the arm, and a chamber to which the contents of the generator have access, substantially as and for the purpose described.

5. In apparatus for governing vapor, oil and similar burners, the combination with lever-regulating mechanism, of a diaphragm, a diaphragm-chamber, a fluid-reservoir communicating with the diaphragm-chamber through a by-pass conduit, a pump communicating through valve-controlled conduits with the diaphragm-chamber and the reservoir, a constantly-moving lever, resilient bodies between the lever and the pump-plunger, a locking-arm, a plug on the arm, and a chamber cooperating with the plug and to which the contents of the generator have access, substantially as and for the purpose described.

6. In apparatus for governing vapor, oil and similar burners, the combination with lever-regulating mechanism, of a diaphragm, a diaphragm-chamber, a fluid-reservoir communicating with the diaphragm-chamber through a by-pass conduit, a regulating device in the conduit, a pump communicating through valve-controlled conduits with the diaphragm-chamber and the reservoir, a constantly-moving lever, resilient bodies between the lever and the pump-plunger, a locking-arm, a plug on the arm, and a chamber cooperating with the plug and to which the contents of the generator have access, substantially as and for the purpose described.

7. In apparatus for governing vapor, oil and similar burners, the combination with lever-regulating mechanism, of a diaphragm, a diaphragm-chamber, a fluid-reservoir, a pump communicating with the diaphragm-chamber and the reservoir, a constantly-moving lever, resilient bodies between the lever and the pump-plunger, a locking-arm, a plug on the arm, a chamber cooperating with the plug and to which the contents of the generator have access, and means between the plug and the chamber for holding the plug stationary, substantially as described.

8. In apparatus for governing vapor, oil and similar burners, the combination with lever-regulating mechanism, of a diaphragm, a diaphragm-chamber, a fluid-reservoir, a pump communicating with the diaphragm-chamber and the reservoir, a constantly-moving lever, resilient bodies between the lever and the pump-plunger, a locking-arm, a plug on the arm, a chamber cooperating with the plug and to which the contents of the generator have access, and a flexible metal between the plug and the chamber, substantially as and for the purpose described.

9. In apparatus for governing vapor, oil and similar burners, the combination with lever-regulating mechanism, of a diaphragm, a diaphragm-chamber, a fluid-reservoir, a pump communicating with the diaphragm-chamber and the reservoir, a constantly-moving lever, resilient bodies between the lever and the pump-plunger, a locking-arm, a plug on the arm, a chamber cooperating with the plug and to which the contents of the generator have access, a cap for the chamber, coating grooves and lips on the cap and the chamber, and means for locking and unlatching the plug controlled by the heat of the contents of the generator passing through the chamber, substantially as described.

696,800. PROCESS OF CONVERTING CELLULOSE INTO SUGAR. ALEXANDER CLARKE, Ashton, Cheshire, England. Filed Dec. 2, 1899. Serial No. 59,269. (No specimens.)

Claim.—1. A process of converting cellulose into sugar consisting in heating cellulose in a closed vessel with sulfuric acid to a temperature from 130° to 145° centigrade, introducing into the mass chlorine to convert part of the sulfuric acid into sulfurous acid, then further heating the mass thus obtained, and then suitably boiling the mass.

2. A process of converting cellulose into sugar consisting in heating cellulose with sulfuric acid to a suitable temperature, introducing into the mass chlorine to convert part of the sulfuric acid into sulfurous acid, then further heating the mass thus obtained, and then suitably boiling the mass.

3. A process of converting cellulose into sugar consisting of heating cellulose with sulfuric acid in a closed vessel to a temperature of 130° to 145° centigrade, introducing into the mass chlorine to convert part of the sulfuric acid into sulfurous acid to effect the conversion of the mass, further heating the mass thus obtained, and then boiling the mass with water in an open vessel.

4. A process of converting cellulose into sugar consisting of heating the cellulose in a closed vessel with sulfuric acid to a suitable temperature, then adding a chlorine-yielding substance to convert the sulfuric acid into sulfurous acid to effect the conversion of the mass, then suitably heating the converted mass, and then suitably boiling the mass.

696,801. PENCIL. CARLOS V. OUTRATT, Lima, Peru. Filed Dec. 11, 1900. Serial No. 59,267. (No model.)

Claim.—1. A pencil-holder consisting of an internally screw-threaded outer tube provided with a plug in one end, a stem secured to the plug and approximately of the same length as the tube, an externally screw-threaded inner tube screwing into the outer tube and having a screw-threaded socket in its outer end, a lead-tube secured into the inner tube and having one end projecting beyond the same, said projecting end being split, and a removable tip having a tapering base and screwing into the socket of the inner tube, as set forth.

2. A pencil-holder comprising an outer internally-screw-threaded tube having one closed end and carrying a centrally-arranged stem, an externally-screw-threaded inner tube screwing into the outer tube and provided with a lead-clamping tube projecting from one end, and a screw-threaded socket concentric with the lead-clamping tube, and a tip screwing into the said socket, as set forth.

3. A pencil-holder comprising two telescopic members, one of said members carrying a lead-tube projecting at one end and therefrom formed with a clamping member, the other member of the holder carrying a stem entering said lead-tube and feeding the lead therefrom as said members are telescoped, and a clamping member secured to the telescoping member carrying the lead-tube and cooperating with the clamping member of the lead-tube to clamp the lead in its adjusted position, substantially as described.

4. A pencil-holder comprising two telescopic members, one of said members carrying a lead-tube having its end projecting therefrom and formed with a clamping portion, the other member carrying a stem entering said lead-tube and feeding the lead therefrom as the members are telescoped, and a removable clamping member attached to the end of the member carrying the lead-tube and cooperating with the clamping portion of said lead-tube to clamp the lead in its adjusted position, substantially as described.

696,802. ADJUSTABLE INVALID-MATRESS. HENRY DARRIN, Des Moines, Iowa. Filed June 7, 1901. Serial No. 62,562. (No model.)

Claim.—1. In an improved mattress, the combination of independent head and foot mattress-sections, and one or more contractile coil-springs passed longitudinally through both sections, each spring having one end connected with the head-section and the other connected with the foot-section, for the purpose stated.

2. In an improved mattress the combination of independent head and foot mattress-sections, and one or more contractile coil-springs passed longitudinally through both sections, and a flexible tube for inclosing each spring, each spring having one end connected with the head-section and the other connected with the foot-section, for the purpose stated.

3. In an improved mattress the combination of head and foot mattress-sections, a cross-piece on the interior of each section, one or more contractile coil-springs passed through both sections in a direction longitudinally of the mattress, flexible ropes attached to the ends of the springs

and passed through said cross-pieces to the exterior of the mattress where by the tension of the springs may be adjusted.

4. An improved mattress, comprising in combination, independent head and foot mattress-sections, a cross-piece at the outer end of each section, springs connected with both of the cross-pieces and passed longitudinally through the sections, rods in the interior of the foot-section having loops or eyes projecting through the section at its inner corners, rods on the interior of the head-section having elongated loops projecting through the inner corners thereof and slidingly connected with the above-aid loops, for the purpose stated.

5. An improved mattress, comprising in combination, independent head and foot mattress-sections, a cross-piece at the outer end of each section, springs connected with both of the cross-pieces and passed longitudinally through the sections, rods in the interior of the foot-section having loops or eyes projecting through the section at its inner corners, rods on the interior of the head-section having elongated loops projecting through the inner corners thereof and slidingly connected with the above-aid loops, and means for adjustably supporting the head-section at different points of elevation relative to the foot-section.

6. The combination with a two-part mattress divided transversely near its central portion, the arms pivotally connected with the outer corners of the head-section, flanged wheels at the lower ends of the said arms and chains having hooks in their ends connected with the lower and portions of said arms, said hooks being designed to engage the links of the chains.

7. The combination with a two-part mattress divided transversely near its central portion, the arms pivotally connected with the outer corners of the head-section, flanged wheels at the lower ends of the said arms and chains having hooks in their ends connected with the lower and portions of said arms, said hooks being designed to engage the links of the chains, and a longitudinally-adjustable cross-piece connecting said arms at their lower portions.

8. The combination with a two-part mattress divided transversely near its central portion, of a flap secured to the inner end portion of the foot-section and means for attaching the forward end of said flap to a part of the bed-frame.

696,808. ANGLE-COCK ADJUSTER FOR AIR-BRAKES. WILLIAM B. DU CAMP, Chillicothe, Ohio. Filed Dec. 31, 1901. Serial No. 87,908. (No model.)

Claim.—1. An angle-cock adjuster comprising pneumatic means for turning the plug of said cock, and a by-pass valve for carrying the air around the angle-cock plug, said by-pass valve being located in the casing of the angle-cock substantially as described.

2. A pneumatic angle-cock adjuster comprising a cylinder a pressure-valve and a piston for turning the angle-cock by increased air-pressure, and a by-pass valve located in the angle-cock casing to pass air around the plug of the angle-cock substantially as described.

3. The combination with the train-pipe and the angle-cock controlling the same; of a cylinder, a coupling for the train-pipe and a valve-cock, all cast in one piece, and a pressure-valve adapted to open into the cylinder at a predetermined pressure substantially as and for the purpose described.

4. An angle-cock having a turning plug with an arm attached thereto and a pneumatic piston and cylinder for working said arm, a valve-chamber opening on opposite sides of the turning plug, and a valve located in said chamber and controlling the passage of air around the plug substantially as and for the purpose described.

5. An angle-cock having a turning plug with an arm attached thereto and a pneumatic piston and cylinder for working said arm, a valve-chamber opening on opposite sides of the turning plug, a valve located in said

chamber and controlling one of said openings, a spring arranged behind the valve, and a removable cap closing the end of said valve-chamber substantially as described.

6. In an angle-cock adjuster, the combination with the plug-arm and its turning-rod; of a pneumatic cylinder and piston for operating the rod, said piston having a hollow tube or sleeve extending through the end of the cylinder and loosely receiving and acting upon the rod which turns the cock-plug substantially as described.

7. In an angle-cock adjuster, the combination with the plug-arm and its turning-rod; of a pneumatic cylinder having an elastic cushion in its end, a piston having a tubular sleeve extending through and closely fitting said cushion and having also a ring or eccentric flange about the sleeve adapted to pinch the cushion at the end of the stroke, substantially as described.

696,804. WARE-LENGTHENING DEVICE. BENJAMIN D. LARRY, Philadelphia, Pa. Filed May 20, 1901. Serial No. 61,001. (No model.)

Claim.—1. A ware-lengthener consisting of an extensible strip of flexible material, having at each end fastening means, that at the upper end comprising a hook turned outwardly and downwardly to engage a bolt, and that at the lower end comprising an engaging eye for the hook of the corset, and means carried by said flexible strip for shortening the connection between the corset and the bolt, substantially as described.

2. In a ware-lengthener, the combination of the draw-bolt, a hooked member adapted to engage the same, a corset, a clamping member carried by the same, and a flexible connection secured to the clamping member and extending from the same to the hooked member and thence to a clamping-plate carried by the clamping member, said flexible connection serving to draw said members together, thereby lowering the bolt at the front giving a pointed and lengthened effect to the draw-body.

3. In a ware-lengthener, the combination of the bolt, a hooked member carried by the same, a corset, a clamping member secured to the same by means of an eye carried thereby, and a strap for connecting said mem-

ber, said strap being secured to the rear of the clamping member, passing up from the same and through the hooked member, and then down through the front of the clamping member, and means for holding it thereat in any desired position.

4. In a ware-lengthener, the combination of a belt, an engaging plate carried thereby, a hooked member secured to said engaging plate, a corset, a fastener for the same, a clamping member carried by said fastener, and a flexible adjustable strap or band connecting the hooked member and the clamping member whereby the same may be drawn together thereby lowering the belt at the front and giving the draw body or waist a pointed and lengthened effect.

696,805. BUT-CRACKER. WILLIAM V. FURNEY, San Antonio, Tex. Filed May 22, 1901. Serial No. 61,373. (No model.)

Claim.—1. A nut-cracking implement, comprising a pair of similarly-bent handle-links pivoted together at the ends, a hammer-block rigidly secured on the opposite end of said link, each hammer-block having a cavity, said cavities being in the ends of the blocks that may have contact with each other, and a guide device on one handle-link near the hammer-blocks and adapted to guide the other link.

2. A nut-cracking implement, comprising a pair of similarly-bent handle-links, pivoted together near the ends of the links, a hammer-block rigidly held on the opposite end of each handle-link, each hammer-block having a cavity, said cavities being formed in opposed ends of the hammer-blocks, a handle-link in each handle-link, and a guide-piece having parallel members affixed by their ends to one of the handle-links, and loosely embracing the other handle-link.

696,806. LIQUTYPE-MACHINE. FREDERICK T. DODGE, Washington, D. C., assignor to Harpeth-Letter Lithotype Company, a Corporation of New York. Filed Feb. 11, 1902. Serial No. 70,008. (No model.)

Claim.—1. In a lithotype-machine, a magazine with spacing or justifying device adjustable to and from the point of composition.

2. In a lithotype-machine and in combination with the matrix-assembler thereunder, a magazine for the spaces adjustable vertically, whereby the time required for the passage of the spaces to the line may be varied.

3. In a lithotype-machine and in combination with an assembler wherein the matrices are composed or assembled in line, a magazine from which the spaces or justifiers are delivered to the line, means for adjusting said magazine to change its distance from the assembler, and keyboard mechanism and adjustable connection between said keyboard and the adjustable magazine, whereby the parts may be caused to deliver spaces from the magazine in either of its positions.

4. In combination with the read F, the yoke R, eccentric S, roller T, yoke-containing dog V, and finger-key W, having in its rear end in direct engagement with said dog, substantially as described and shown.

696,807. ELECTRIC-ARC LAMP. RENE FRANCHET, Paris, France. Filed Sept. 7, 1901. Serial No. 74,504. (No model.)

Claim.—1. An electric-arc lamp, a regulator comprising the combination of an electromagnet, a lower central core movable within said electromagnet and rigidly connected with but electrically insulated from the upper carbon, a counter-spring lodged in the said core and adapted to be compressed between this latter and a movable cap arranged above and in the axis of the electromagnet, two brushes pivoted and bearing upon the movable cap and adapted to wedge the guide-rods in such a manner that the tension of the spring combined with the attraction of the core permits of fixing the regulator or of causing it to slide as a whole in order to maintain constant the interval separating the carbons and consequently the intensity of the current.

2. An arc-lamp, comprising a pair of guide-rods, a frame slidably mounted upon said guide-rods and provided with friction-brakes for engaging the same, a solenoid provided with a member for modifying the magnetic field, an armature made in sections, one of which is stationary relatively to said solenoid and the other movable relatively thereto, brushes mounted upon said frame and connected with said movable section of said armature, means for mounting a carbon upon said movable section and for connecting another carbon with said guide-rods, and means for supplying an electrical current to said solenoid and said carbon.

3. An arc-lamp comprising a pair of guide-rods, a frame slidably mounted thereon, a cap loosely mounted upon said frame and movable relatively thereto, an electrically-operated device for actuating said cap relatively to said frame, brake-shoes carried by said frame and normally free to grip said guide-rods, levers connected with said brake-shoes and provided with free ends, said free ends resting loosely upon said cap to compensate virtual differences in the space between said guide-rods at various points.

696,808. MOTOR-FLOW. EDWARD J. GATLIN, St. Louis, Mo. Filed July 12, 1901. Serial No. 60,712. (No model.)

Claim.—1. In an agricultural implement of the character described, the combination of a frame, a carrier, a series of soil-working members connected to said carrier, and adjustment means connected to each end of said carrier and to said frame, whereby the angle of said carrier may be altered, substantially as described.

2. In an agricultural implement of the character described, the combination of a frame, a carrier, a series of soil-working members connected to said carrier, adjustment means forming connection between the ends of said carrier and said frame, and adjustable stay-rods providing connection between the carrier and frame intermediate of the ends of said carrier, substantially as described.

3. In an agricultural implement of the character described, the combination of a frame, a carrier, a series of soil-working members connected to said carrier, and adjustable connections between said carrier and frame, whereby said carrier may be tilted, substantially as described.

4. In an agricultural implement of the character described, the combination of a frame, a carrier, a series of soil-working members connected to said carrier, a pair of connecting-rods attached to said carrier and adjustably connected to said frame, substantially as described.

5. In an agricultural implement of the character described, the combination of a frame, a cross-bar carried thereby, a carrier, a series of soil-working members connected to said carrier, means whereby said rods are adjustably held to said cross-bar, a pair of stay-rods attached to said carrier, eyes on said frame in which said stay-rods are seated, and adjustment-means on said stay-rods at opposite sides to said eyes, substantially as described.

6. In an agricultural implement of the character described, the combination of a frame, a carrier connected to said frame, a series of soil-working members swingingly and independently connected to said carrier, and means whereby said soil-working members may be shifted to vary the angle thereof with relation to the ground in which they operate, substantially as described.

7. In an agricultural implement of the character described, the combination of a frame, a carrier connected to said frame, a series of hangers independently pivoted to said carrier, soil-working members journaled in said hangers, and means for rocking said hangers on their pivots to vary the angle of the soil-working members with relation to the ground in which they operate, substantially as described.

8. In an agricultural implement of the character described, the combination of a frame, a carrier connected to said frame, a series of hangers independently pivoted to said carrier, soil-working members mounted on said hangers, and a shift-bar arranged in engagement with said hangers and adapted to shift said hangers in unison, substantially as described.

9. In an agricultural implement of the character described, the combination of a frame, a carrier connected thereto, a series of hangers independently pivoted to said carrier, soil-working members mounted on said hangers, and an adjustable slide-bar arranged in engagement with said hangers and adapted to shift said hangers in unison, substantially as described.

10. In an agricultural implement of the character described, the combination of a frame, a carrier connected to said frame, a series of hangers pivoted to said carrier, soil-working members mounted on said

hangers, a notched slide-bar having engagement with said hangers, and means for adjusting said slide-bar, substantially as described.

11. In an agricultural implement of the character described, the combination of a frame, a carrier connected to said frame, a series of hangers pivoted to said carrier and provided with lugs, soil-working members mounted on said hangers, a notched slide-bar having engagement with the lugs of said hangers, and means for shifting said slide-member longitudinally to rock said journal members in unison, substantially as described.

12. In an agricultural implement of the character described, the combination of a frame, a carrier connected to said frame, a series of soil-working members connected to said carrier at the rear side thereof, and restraining members connected to said carrier at the front side thereof, said last-named members being arranged to resist the longitudinal movement of said carrier, substantially as described.

13. In an agricultural implement of the character described, the combination of a frame, a carrier connected to said frame, a series of soil-working members connected to said carrier at the rear side thereof, and reversible disks mounted upon said carrier at the front side thereof adapted to resist the longitudinal movement of said carrier incident to the strain exerted upon the soil-working members, substantially as described.

14. In an agricultural implement of the character described, the combination of a frame, a carrier connected to said frame and arranged at an angle to the path of travel of the implement, a series of soil-working members connected to said carrier, and a flexible stay connected to the rear end of said carrier and to said frame, substantially as described.

696,809. HYDRAULIC MOTOR. JAMES C. CHILLY, Paris, France. Filed Jan. 24, 1901. Serial No. 44,512. (No model.)

Claim.—1. A hydraulic motor, comprising a reservoir, a tube depending from the same and entering below the surface of a body of water of lower level, a current-operated valve connected to a power-transmitting rod for closing said tube, the arrangement of the parts being such as to form successively partial vacuums in the tube for the purpose of utilizing the pressure due to the entire depth of water from the surface water in the reservoir to the surface of the water below.

2. A hydraulic motor, comprising a reservoir, a discharge-tube depending therefrom and entering below the surface of a body of water of lower level, an automatic valve connected to a power-transmitting rod for intermittently closing said tube, and a spring for normally holding said valve open, the arrangement being such that the sudden closing of the tube causes the volume of water in the tube to rebound and thereby assist the spring in opening the valve.

3. A hydraulic motor comprising a cylinder open at one end to a body of water, a pipe leading from the opposite end of the cylinder to another body of water at a lower level and immersed therein, a poppet-valve held to reciprocate in the cylinder and controlling the communication of the cylinder with the said pipe, and a power-transmitting rod connected with said poppet-valve.

4. A hydraulic motor comprising a cylinder open at one end to a body of water, a pipe leading from the opposite end of the cylinder to an-

other body of water at a lower level and immersed therein, a poppet-valve held to reciprocate in the cylinder and controlling the communication of the cylinder with the said pipe, a spring opposing the movement of the poppet-valve toward its seat, and a power-transmitting rod connected with said poppet-valve.

5. A hydraulic motor comprising a cylinder open at one end to a body of water, a pipe leading from the opposite end of the cylinder to another body of water at a lower level and immersed therein, a poppet-valve held to reciprocate in the cylinder and controlling the communication of the cylinder with the said pipe, said poppet-valve being arranged to move up and down, and a power-transmitting rod connected with said poppet-valve.

6. A hydraulic motor comprising a cylinder open at one end to a body of water, a pipe leading from the opposite end of the cylinder to another body of water at a lower level and immersed therein, a poppet-valve held to reciprocate in the cylinder and controlling the communication of the cylinder with the said pipe, said poppet-valve being free to reciprocate, and a power-transmitting rod connected with said poppet-valve.

696,810. NECKTIE-FASTENER. GEORGE G. SMITH, Baltimore, Md. Assignor to Adolph Hollander, New York, N. Y. Filed Oct. 2, 1901. Serial No. 77,222. (No model.)

Claim.—1. As an article of manufacture, a necktie-fastener, comprising a plate of sheet metal, provided with one end with fastenings secured to a necktie-shoulder, a Y-shaped clasp pivoted to said plate and provided with a hook-like member terminating in pointed feet, and a torsional spring engaging said plate and said clasp, for normally holding said Y-shaped member in such a position that said pointed feet engage said plate.

2. As an article of manufacture, a necktie-fastener, comprising a plate of sheet metal provided with a central boss and with means for securing said plate to a shirt, a Y-shaped clasp pivoted to said plate and provided with legs terminating in pointed feet, and a torsional spring engaging said plate and said Y-shaped clasp.

3. As an article of manufacture, a necktie-fastener comprising a plate of sheet material provided with a substantially hemispherical boss integral therewith, means for securing said plate to a shirt, a Y-shaped clasp pivoted to said plate and provided with a hook-like member integral therewith, said hook-like member having V-shaped points for limiting its rocking movement, and a torsional spring engaging said plate and said Y-shaped clasp.

696,811. RAILWAY SIGNALING AND COMMUNICATING APPARATUS. HARRY GILBERT, South Yarra, Victoria, Australia. Filed July 2, 1901. Serial No. 67,090. (No model.)

Claim.—1. In a signaling system of the character described, a track, a conductor arranged along said track, a vehicle adapted to travel on said

track, a tower, an electric generator in said tower connected with the conductor, the connections including a contact-maker, a brush on said vehicle adapted to engage said conductor, signal devices on the vehicle electrically connected with said brush, a hand-lever in the tower, and means operated by said hand-lever for actuating said contact-maker.

2. In a signaling system of the character described, a track, a conductor arranged along said track, a vehicle adapted to travel on said track, a tower, an electric generator in said tower connected with the conductor, the connections including a contact-maker, a brush on said vehicle adapted to engage said conductor, signal devices on the vehicle electrically connected with said brush, a lever connected to said contact-maker, a sliding rod for operating said lever, a hand-lever, and a cam connected with said hand-lever for operating said sliding rod.

3. In a signaling system of the character described, a track, a conductor arranged along said track, a vehicle adapted to travel on said track, a tower, an electric generator in said tower connected with the conductor, the connections including a contact-maker, a brush on said vehicle adapted to engage said conductor, signal devices on the vehicle electrically connected with said brush, a hand-lever, a slide, a cam operable by said hand-lever and adapted to actuate said slide, and connections between said slide and the contact-maker for operating the latter.

696,812. STRAW-STACKER. ARTHUR HACHENBERGER, Altona, N. D. Filed July 2, 1901. Serial No. 67,217. (No model.)

Claim.—1. In a straw-stacker, a support, fan-casing mounted thereon, a hopper between said fans provided with an outlet extending beyond the said casing, the portion of the front wall of the hopper forming the rear wall of one of the fan-casings and terminating near the entrance to said outlet, a fan in each casing, and means for operating the same, substantially as described.

2. In a straw-stacker, a support, three fan-casing mounted thereon, two of which are at a distance from each other laterally, and the other one is located in front of and substantially on a line between the said two casings, a hopper between said casing and the two casings provided with an outlet which communicates with all of said casings, a fan in each casing and means for operating the same.

3. In a straw-stacker, a support, three fan-casing mounted thereon, two of which are at a distance from each other laterally, and the other one is at a distance in front of and on a line between said two casings, a hopper between said casing and the two casings provided with an outlet which communicates with each of said casings, three shafts mounted upon said support, all of which extend into said two casings respectively, and the other one extends entirely through the front casing, a fan upon each shaft within its respective casing, pulleys upon said shafts and belting upon said pulleys operating said two shafts from the shaft through the front casing, substantially as described.

4. In a straw-stacker, the support, three fan-casing mounted thereon, one of which is in front of the other two, a hopper between said front casing and the two rear casings, a delivery-chute communicating with said hopper and the fan-casings the bottom wall of which is formed by an extension of the bottom of the front casing and the top intersects the adjacent walls of the two casings near the center and is joined to the rear wall of the hopper, a fan in each casing, and means for operating the same.

5. In a straw-stacker, a support, casings mounted thereon, two of which are at a distance from each other laterally, and each has substantially the lower half of its inner wall cut away and provided with a centrally-located bearing, and the other casing is in front of and substantially on a line between said two casings, a hopper between said front casing and the two rear casings, a portion of the front wall of which forms the rear wall of said casing and terminates with the space formed by said cut-away portions, a delivery-chute communicating with said hopper and casings, the lower wall of which is substantially an extension of the bottom of said forward casing, and the upper wall joins the edge of the cut-away portions of said inner walls, a fan in each casing, the shafts of the case in said two casings being each journaled in the bearing on the inner wall of its respective casing, and the other shaft extending entirely through its casing, and means for operating the said two fans from the shaft of the one fan, substantially as described.

696,818. BOX. WALTER J. HARRISON, Boston, Mass. Filed May 25, 1901. Serial No. 61,999. (No model.)

Claim.—1. The herein-described box, consisting of the top *a*, the bottom *b*, the ends *c* and *d*, the end *e*, provided with a suitable catch; the side pieces *f* and *g*, secured to the top portion of the box and the side pieces *h* and *i*, secured to the bottom part of the box, and having the upper corner at *j* slightly recessed, and the parts *k* and *l*, suitably pivoted to the end piece *c*, so that the upper part of the box may be removed or swung upwardly from the lower part of the box, substantially as and for the purpose set forth.

2. In a box consisting of two parts, one part forming the upper portion having the top *a*, of the length and substantially of the width of the box, and with two side pieces *b* and *c*, of the length of the box, and with substantially the depth of the box for a portion of their length, and each hinged from substantially the middle of its length upwardly toward one end, and the whole secured together as one portion; in combination with the said second part, consisting of the bottom *d*, formed of the full size of the box, and having two parallel side pieces *e* and *f*, widest at the outer ends and extending to a point midway of the length of the box, and the end piece *g*, and all secured together as one portion; the levels of the upper and lower parts coinciding and all adapted to operate substantially as set forth.

3. In a box consisting substantially of two parts, the top part *a*, pivoted at one end and having the sides *b* and *c*, provided with the bevel *d*, secured to the top piece and one end of the box; and the bottom part *e*, having the bevel pieces *f* and *g* secured to the bottom piece and the opposite end of the box, *h*, combined and arranged substantially as set forth.

4. In a box, without partitions, the bottom *a*, formed the length and width of the box, and secured to the end piece of the box *b*; two side pieces *c* and *d*, the said side pieces being widest at the outer ends, and hinged to a point midway of the length of the box, and secured to the bottom *a*, and end piece *e*, and adapted to hold the contents of the box in place when resting on the said bottom, and while the rest of the box is removed from its normal position, substantially as set forth.

696,814. PLURAL WHISTLE. ALEXANDER F. HARRIS, Bridgeport, Conn. Filed Sept. 14, 1901. Serial No. 75,477. (No model.)

Claim.—A whistle consisting of a central valve-chamber, a mouth-piece leading thereto, a plurality of barrels leading out from the central chamber, and a corresponding number of partitions or valves between the valve-chamber and the barrels, said valves or partitions being flush with the walls of the mouthpiece at the point of junction therewith, the opposite edges of the valves or partitions being cut away to form openings 10 and each partition having a base or leg 11 to serve as a support for the walls of the barrels to preserve the shape of the opening 10, the barrels being formed with openings corresponding to the openings 10, substantially as described.

696,815. GAS-BURNER FOR STOVES. HARVEY J. HENRY, Mass. Filed Dec. 31, 1901. Serial No. 60,766. (No model.)

Claim.—In a gas-burner for stoves, the combination of a shell, a supply-pipe connected thereto, partitions located in the shell and spaced from each other, gas-passages located between the partitions and the shell, a cover spaced from the shell and said cover provided with an annular flange having a concave bottom or under side and a series of apertures located through the flange having the concave bottom, a plate located over the passages between the partitions in the shell and the plate provided with apertures, substantially as and for the purpose specified.

696,816. ROLLER-DIE. HENRY HENSON, Wilkes-Barre, Pa. Filed Dec. 14, 1901. Serial No. 60,948. (No model.)

Claim.—1. A roller-die for forming angular projections integrally on metal plates and the like, comprising a roller mounted to turn and having a peripheral beveling-face and a peripheral cutting edge, and means for moving the roller bodily in engagement with the plate, and in the direction in which the projection is to extend, whereby the roller is caused to turn in a direction toward the plate to cut the plate, the roller at the same time beveling the end portion, as set forth.

2. A roller-die for forming angular projections integrally on metal plates and the like, comprising a roller mounted to turn and having a peripheral beveling-face, peripheral cutting edges at the ends of the roller, and means for moving the roller bodily in engagement with the plate and in the direction in which the projection is to extend, whereby the roller is caused to turn in a direction toward the plate, as set forth.

3. A roller-die for forming angular projections integrally on metal plates and the like, comprising a roller mounted to rotate, and having a peripheral beveling-face and a peripheral cutting edge, means for moving the roller bodily in engagement with the metal plate, and in the direction in which the projection is to extend, whereby the said roller is caused to turn in a direction toward the plate and a bed-plate or support for supporting the plate, and having an abutment for the projection to be pressed against by the roller, as set forth.

4. A roller-die for forming angular projections integrally on metal plates and the like, comprising a support for the plate, a roller having a peripheral beveling-face and a peripheral cutting edge, a support in which the roller is mounted to turn, and adapted to be moved vertically downward to carry the roller bodily in contact with the upper side of the plate near one edge thereof, the point of contact of said roller with the plate being at one side of its axis, whereby the roller when forced in contact with the plate is caused to rotate in a direction toward the plate and the cutting force of the roller is applied in direction of the top surface of the plate, thereby insuring a clean cut at the inside corner in the plate, the roller at the same time beveling the end portion downward, as set forth.

696,817. TURNING DEVICE. GEORGE E. HARRIS, Seattle, Wash. Filed Jan. 21, 1903. Serial No. 60,664. (No model.)

Claim.—1. A turning device, comprising a cutter, means for centering and rotating an object to be turned, and a tank containing a liquid for floating said object while being turned.

2. A turning device, comprising means for centering and rotating an object to be turned, a tank for floating said object, and a revolvable cutter free to move bodily adjacent to said object to be turned.

3. A turning device, comprising means for centering and rotating an object to be turned, a longitudinal tank for floating said object, and a traveling carrier having a depending arm provided with a revolvable cutter, the said carrier being free to move in a direction substantially parallel with said horizontal tank.

4. A turning device, comprising a longitudinal tank for holding liquid, longitudinal tracks located substantially parallel thereto, means for centering and rotating an object in said tank so as to float therein, overhead tracks substantially parallel with said tank, posts for supporting said tracks, means for adjusting said tracks relative to said posts, and a cutting device for operating upon the object to be turned.

5. A turning device, comprising a longitudinal tank for holding liquid, longitudinal overhead tracks located substantially parallel to said tank, means for centering and rotating an object in the tank, a traveling carrier mounted upon said tracks and provided with a depending arm, a frame provided with a threaded member for engaging said arm and thereby adjustable relatively to said carrier, revolvable cutters mounted upon said frame and movable bodily therewith, and means for actuating said cutters.

6. A turning device, comprising means for centering and rotating an object to be turned, a tank for holding a liquid for floating said object, supports for centering said object independently of said means for centering and rotating and also independently of said liquid, and operating mechanism for cutting the object to be turned.

7. A turning device, comprising means for centering and rotating an object to be turned, a longitudinal tank for floating said object, longitudinal tracks located substantially parallel with the general direction of said tank, a traveling carrier having a depending arm provided with a revolvable cutter for engaging the object to be turned, mechanism for actuating said cutter, and means for adjusting the position of the said tracks relative to the position of said tank.

696,818. DELIVERY-TABLE FOR PRINTING-PRESS. EDWARD M. HOWELL, Denver, Colo. Assignor to Howell and Peter J. Thomas, Denver, Colo. Filed July 13, 1901. Serial No. 62,767. (No model.)

Claim.—1. The combination of a delivery-table, a series of posts adjustable radially thereon, and jagger-boards clamped to said posts and adjustable longitudinally thereon, said jagger-boards being also adjustable

with the posts and occupying an abutting and overlapping relation one to the other, whereby the jagger-boards are adapted to form a paper-receiving space of any dimensions within the limits of the jagger-boards.

2. The combination of a delivery-table having radial guideways, a series of posts adjustable in said guideways and provided with means for holding the same in place, a single group of jagger-boards mounted on the posts for adjustment therewith and each jagger-board adjustable in the direction of its length on said post and jagger-boards arranged in abutting and overlapping relation and forming a paper-receiving space or chamber which is closed on all sides, and means for clamping each jagger-board firmly to one post.

3. The combination with a table, and a slide, of a post removably fitted to the slide, a locking-plate carried by the slide and having interlocking engagement with the post, and a jagger-board said locking-plate serving to hold the post in a rigid predetermined position relative to the slide and against any tendency to lateral displacement under the wear incident to service.

4. The combination with a table, and a slide, of a post fitted to said slide and having a leg, a locking-plate pivoted to the slide and adapted to engage said leg, means for clamping the locking-plate in position, and a jagger-board.

5. A delivery-table having suitable guideways, slides adjustable on said guideways in the direction of the length thereof, supports removably secured on said slides, and jagger-boards clamped to said supports and adjustable thereon in the direction of the length of said jagger-boards, said jagger-boards being adjustable with the slides and also adjustable independently thereon, whereby the jagger-boards may be brought into abutting and overlapping relation one with the other and to form a paper-receiving space of any area within the limits of the jagger-boards.

6. A delivery-table having intersecting guideways, slides adjustable in said guideways, supporting posts removably secured on said slides, a locking device carried by each slide and having interlocking engagement with one post for locking the latter in a rigid predetermined position relative to said slide, and a group of jagger-boards mounted individually on said posts and disposed in abutting and overlapping relation.

7. A delivery-table having an adjustable post provided with a leg, a jagger-board having a recess, a slotted plate attached to the jagger-board and receiving the leg of said post, a nut confined in the recess of the jagger-board, and a thumb-screw supported by the post and engaging said nut.

8. In a delivery-table, a single group of jagger-boards disposed in abutting and overlapping relation and forming an inclosed paper-receiving space which is closed on all sides, combined with a table, and supporting devices adjustable radially on said table; said jagger-boards being adjustable with the supports and also capable of independent end-wise adjustment on said supports.

9. In a delivery-table, the combination with a carrier-slide and an supporting post removably mounted on said slide, of a separate locking device connected with said slide and with the post and holding the latter in a rigid predetermined position relative to the slide, and a jagger-board supported on the post.

696,819. LOCK-LOCK. DANIEL HOTT, South Norwalk, Conn. Assignor of one-half to the National Lock Washer Company, Norwalk, N. J., a Corporation of New Jersey. Filed Jan. 2, 1903. Serial No. 62,175. (No model.)

Claim.—A lock-lock comprising upper and lower eccentric locking-eyes having rearwardly-extending operating-levers, said locking-eyes being provided with contacting operating-ears, the operating-ear upon the upper locking-eye lying in front of the operating-ear upon the lower locking-eye, so that upward movement of the lower lever will disengage both locking-eyes but downward movement of the upper lever will only disengage the upper locking-eye having the lower locking-eye in the locking position.

696,820. LOCK-GAME. DANIEL HOTT, South Norwalk, Conn. Assignor of one-half to the National Lock Washer Company, Norwalk, N. J., a Corporation of New Jersey. Filed Jan. 2, 1903. Serial No. 62,176. (No model.)

Claim.—A case of the character described comprising a case proper provided with integral posts, an integral abutment 13 shorter than the posts, an integral abutment 15 the height of the posts and having a shoulder the height of abutment 13 and recesses at its upper and lower ends, the bottoms of which are of uniform height with abutment 13 and the shoulder on abutment 13, and are provided at their rear ends with solid walls and a back plate resting upon abutment 13, the shoulder on abutment 15 and the bottoms of the recesses and bearing against abutment 15 and the walls at the ends of the recesses.

**696,821. APPARATUS FOR PRESSING, STAMPING, EMBOS-
ING, OR PLUNTING FLAY SURFACES.** CARL HEDER, Karlsruhe, Ger-
many, assigner to Gesellschaft für Lederpressung Gesellschaft mit
beschränkter Haftung, Karlsruhe, Baden, Germany, a Corporation of
Germany. Original application filed Feb. 4, 1901, Serial No. 45,982.
Divided and this application filed Jan. 12, 1902. Serial No. 92,241.
(No model.)

Claim.—1. Apparatus for pressing stamping embossing or printing flat surfaces comprising a water-chamber whose walls are formed of flexible material extending continuously all around, a strong receptacle con-
fining said water-chamber so as to leave only the surface which is to exert pressure exposed, and means for bringing the surface to be impressed together with the surface for producing the impression thereon into forcible contact with the said exposed surface of the chamber, substantially as described.

2. Apparatus for pressing stamping embossing or printing flat surfaces comprising a water-chamber whose walls are formed of flexible material extending continuously all around, a strong receptacle confining said chamber so as to leave only the surface which is to exert pressure exposed, and having its walls extended beyond such surface, a bed-plate carrying the surface to be impressed and the surface for producing the impression and adapted to fit within the projecting walls of the strong receptacle, and means for bringing the surface to be impressed into forcible contact with the exposed surface of the water-chamber substantially as described.

3. Apparatus for pressing stamping embossing or printing flat surfaces comprising a water-chamber whose walls are formed of flexible material extending continuously all around, a strong receptacle confining said chamber so as to leave only the surface which is to exert pressure exposed, means for forcing liquid under pressure into said chamber, and means for bringing the surface to be impressed together with the surface for producing the impression thereon into forcible contact with the said exposed surface of the chamber, substantially as described.

696,822. BEATING-ENGINE. EDWARD A. JOSE, Pittsfield, Mass.
Filed July 9, 1901. Serial No. 67,267. (No model.)

Claim.—1. A beating-engine having a device in a vat for forcing a stream of water into or under the pulp in the direction in which the pulp is flowing, said device having a discharge-slot extending from one side of the vat to the said-furrow thereof, as set forth.

2. A beating-engine having a device in a vat for forcing a stream of water into or under the pulp in the direction in which the pulp is flowing, said device comprising a pressure-chamber extending from one side of the vat to the said-furrow at the bottom of the vat, said pressure-chamber having a discharge-opening and a connection with the fluid-pressure supply, as set forth.

3. A beating-engine having a device in a vat for forcing a stream of water into or under the pulp in the direction in which the pulp is flowing, said device comprising a pressure-chamber arranged under the rear wall of the backfill and extending from one side of the vat to the said-

furrow, said pressure-chamber having a discharge-opening and a connection with a fluid-pressure supply, as set forth.

696,823. PLANTER AND CULTIVATOR. JAMES R. JOHNS, Jack-
son, Minn. Original application filed Mar. 7, 1901, Serial No. 50,185.
Divided and this application filed July 12, 1901. Serial No. 63,010.
(No model.)

Claim.—1. In planters and like machines, a furrow-opening wheel having its periphery inclined from the center in direction of its sides and provided with a central peripheral rib, and a covering-wheel arranged in tandem with the furrow-opening wheel, the covering-wheel having its periphery also inclined from the center in direction of its sides, the said covering-wheel having a central peripheral groove, as and for the purpose set forth.

2. In planters and like machines, the combination, with the main frame, supporting-wheels for the forward portion of said main frame, and a mechanism for raising and lowering the supporting-wheels, of a furrow-

opening-wheel mounted to turn in the main frame near its center, the periphery of which wheel is inclined from the center in direction of its sides and is provided with a central peripheral rib, and a covering-wheel arranged in tandem with the furrow-opening wheel, the peripheral portion of which covering-wheel is inclined from its center in direction of its sides and is provided with a central peripheral groove in track relation to the rib upon the furrow-opening wheel, as specified.

3. A planter or the like, comprising a frame, rearwardly-extending arms pivotally mounted upon the frame, means for locking the arms in position, supporting-wheels mounted in the forward ends of the said arms, a furrow-opening wheel mounted in the frame in rear of the supporting-wheels, said wheel having its periphery inclined from the center in direction of the sides and provided with a central peripheral rib, and a covering-wheel mounted in the frame in rear of the furrow-opening wheel, said covering-wheel having its periphery inclined from the center in direction of its sides and provided with a central peripheral groove, as set forth.

696,824. WOOD-TURNING MACHINE. WILLIAM T. JOHNS, New Westminster, Canada, assignor of one-half to Henry Doyle, San Francisco, Cal. Filed July 26, 1901. Serial No. 66,791. (No model.)

Claim.—1. In a wood-turning machine, a plurality of saws arranged in axial alignment for cutting off blocks, means for supporting the wood transversely of the saws, means for carrying the blocks from the saws, a series of knives, and means for moving the blocks in axially-aligned pairs past the knives with a rotary motion, substantially as specified.

2. In a wood-turning machine, a plurality of saws arranged in axial alignment for cutting off blocks from a strip of wood, means for supporting the wood transversely of the saws, means for moving the blocks in axially-aligned pairs simultaneously from the saws, boring-tools for forming holes lengthwise in the blocks, means for moving the blocks to and from said boring-tools, a series of knives, and means for moving the blocks past the knives with a rotary motion, substantially as specified.

3. In a wood-turning machine, a pair of saws arranged side by side, one saw being of larger diameter than the other, means for supporting the work transversely to the plane of the saws, a swinging frame in which the saws are mounted, means for moving said frame, boring-tools, means for moving the blocks to the boring-tools, means for moving the blocks onto and off the boring-tools, two series of spindles for receiving the blocks, a series of cutters or knives, and means for moving said spindles carrying the blocks past the cutters, substantially as specified.

4. In a wood-turning machine, a plurality of saws in axial alignment and having a swinging motion, means for causing said swinging motion, opposite boring-tools, means for rotating said boring-tools, means for carrying blocks to the said boring-tools, means for supporting the work to be moved transversely of the saws, means for moving the blocks onto and off from said boring-tools, a reel, means for rotating the reel, a series of spindles for each saw carried by said reel and having a rotary and a longitudinal movement in the reel, means for carrying the blocks from the boring-tools to the reel to be engaged by the spindles, means for rotating the spindles while moving with the reel, and a series of cutters arranged concentrically with the reel, substantially as specified.

5. In a wood-turning machine, a plurality of saws of different diameters, means for moving said saws toward and from a strip of wood from which blocks are to be covered, means for supporting the stick of wood transversely to the saws, boring-tools, means for moving the covered blocks from the saws to the boring-tools, a reel, two series of spindles carried by said reel and mounted to rotate and to move longitudinally therein, means for causing the rotary movement of the spindles while the reel is rotated, means for forcing the spindles into the holes bored in the blocks, cutters arranged concentrically with the reel for operating on said blocks, and means for withdrawing the spindles from the blocks after passing the last of the cutters, substantially as specified.

6. In a wood-turning machine, a plurality of saws for simultaneously covering blocks from a stick, opposite boring-tools, means for rotating said boring-tools in opposite directions, means for directing a stick transversely of the saws, a block table or chute, a frame movable thereon, swinging fingers carried by said frame for engaging with the blocks and moving them along, means for moving said frame and fingers, a reel, two sets of spindles carried by the reel and having rotary and longitudinal movement therein, cutting-blades arranged concentric with the reel, means for imparting motion to the reel, means for rotating the spindles with the blocks, and means for withdrawing the spindles from finished work after leaving the last of the knives, substantially as specified.

7. In a wood-turning machine, the combination with cutters, of a reel, comprising a shaft, a center spindle mounted on the shaft and having openings or bearings in its periphery, pairs of spindles on opposite sides of said center spindle and having bearings, spindles mounted to rotate in the bearings of the said side pairs of spindles and also to move longitudinally therein, the said spindles having end portions to engage in the bearings of the center spindle, means for rotating the spindles and means for rotating the reel, substantially as specified.

8. In a wood-turning machine, a plurality of cutting-blades arranged in the segment of a circle, each of said blades having separated cutting-surfaces for operating upon a plurality of blocks arranged in axial line, and means for moving the blocks in axial pairs past the cutting-blades, substantially as specified.

9. In a wood-turning machine, a reel, block-engaging spindles mounted in said reel, so as to rotate and to move longitudinally, the spindles being arranged in pairs, one spindle of a pair being in axial line with the other spindle of the pair, means for moving said spindles inward to engage in openings formed in the blocks, segmentally-arranged cutting-blades, means for holding the spindles in the blocks while moving past said cutting-blades, a center spindle on the reel coacting with both series of spindles, means for drawing the spindles outward from the blocks, means for rotating the spindles, and means for rotating the reel, substantially as specified.

10. In a wood-turning machine, a pair of saws arranged side by side, a swinging frame in which the saws are mounted, means for swinging said frame, opposite engagers fixed as to longitudinal movement but having means for rotating the same, means for moving blocks of wood to the engagers, block-carriers for receiving said blocks, means for moving said carriers laterally onto and off the engagers, and turning or cutting devices for operating upon the blocks of wood, substantially as specified.

11. In a wood-turning machine, a pair of saws in axial alignment, a block-chute in which the saws operate, a frame movable in side portions of the chute, means for moving the frame back and forth, fingers mounted to swing relatively to the frame, means for supporting a stick transversely of the saws, cutting devices for receiving blocks from said block-chute, spring-fingers at the outlet end of said block-chute, and duplicate means for engaging the blocks held by said spring-fingers and carrying them along the cutters, substantially as specified.

12. In a wood-turning machine, a reel comprising a center spindle having a plurality of transverse openings or bearings in its periphery, bar-cutters at the opposite ends of said openings, spindles at the opposite sides of the center spindle, said spindles having bearings for spindles, spindles mounted to rotate and to move longitudinally in said side spindles, the spindles adjacent to the center spindle having bar-cutters at the inner ends of their openings, cutting-knives arranged concentrically with the reel, means for rotating the reel to carry blocks of wood against the cutting-knives, the said blocks of wood being supported by the spindles, means for rotating the spindles, and means for moving the spindles longitudinally in the spindles, substantially as specified.

13. In a wood-turning machine, a pair of saws operating to simultaneously cover two blocks from a stick, a swinging frame in which the saws are mounted, a block chute or table in which the saws are movable, means for moving covered blocks along said chute or table, means for separating opposite blocks one from the other as they move along the chute or table, cutting-knives, means for supporting a stick transversely of the saws, and means for carrying the blocks in pairs from the chute or table to the cutting-knives, substantially as specified.

14. In a wood-turning machine, a plurality of saws, means for mov-

ing said saws toward and from a strip of wood to be operated upon, a chute or table in which the blocks are movable, means for moving the blocks along said chute or table, laterally-movable carriages for the blocks, adjustable holding devices on said carriages, means for moving said carriages simultaneously in opposite directions, a reel, a double row or set of spindles carried by said reel and adapted for engaging with the blocks as received from the chute or table, means for rotating said spindles on the reel rotatably, and cutting-knives against which the blocks are moved by the reel, substantially as specified.

696,835. ROTARY ENGINE. ISRAEL V. KETNER, Brooklyn, N. Y. Filed Sept. 27, 1901. Serial No. 70,731. (No model.)

Claim.—1. In an engine, the combination of a cylinder, a piston therein, a valve-chest communicating with the cylinder, an oscillating valve mounted in the valve-chest, the stem of the valve projecting beyond the wall of the chest, a sector fastened to said projected stem and having at each edge a laterally-projected part, an arm mounted loosely on the valve-stem, and means for adjustably fastening said arm to a relatively stationary part of the engine.

2. The combination of a circular cylinder, a rotary piston mounted therein and having a shoulder to bear the steam-pressure, a valve-chest, a valve mounted to rock therein, said valve having two steam-ports leading into the cylinder, and a steam-chest having two ports designed respectively to register with the ports in the valve, whereby to connect the steam-chest with the cylinder, the ports in valve and in the steam-chest being different distances apart for the purpose specified.

3. The combination of a circular cylinder, a rotary piston mounted therein and having a shoulder to bear the steam-pressure, a valve-chest, a valve mounted to rock therein, said valve having two steam-ports leading into the cylinder, and a steam-chest having two ports designed respectively to register with the ports in the valve, whereby to connect the steam-chest with the cylinder, the ports in valve and in the steam-chest being different distances apart for the purpose specified, the steam-chest having a third port and the valve having a cavity adapted to register with the third port, when the valve is raised clear of the piston.

4. The combination of a cylinder, a piston, a valve-chest, a rocking valve therein, the valve having a steam-port and also having a cavity at one side of its center of movement, and a steam-chest having a port registering with the steam-port of the valve and also having a port registering with the cavity in the valve when the valve is raised clear of the piston.

696,836. SHUTTLE-GUARD FOR LOOM. JAMES F. LANE, Patents, N. J. Filed May 23, 1901. Serial No. 68,298. (No model.)

Claim.—1. A shuttle-guard, comprising approximately triangular end plates, cross-bars held on said plates, pivot-pins located on the top opposite corners of the plates and extending in opposite directions, one set of pins pivotally connecting the plates to a hand-roll, links connected with the other set of pivot-pins and provided with cushioning means, and adjustable connections between the links and the loom-frame, as set forth.

2. A shuttle-guard, comprising end plates pivoted to a hand-roll and provided with apertures counterbored on the inner face of the plates, cross-bars held on said end plates, and links connecting the end plates with the loom-frame, as set forth.

3. A shuttle-guard, comprising end plates pivoted to a hand-roll, cross-bars held on said end plates, and extension-links, comprising rods connected with the end plates, and tubes connected with the loom-frame and in which the rods telescope, the tubes being provided with cushions, as set forth.

4. A shuttle-guard having end plates, cross-bars held on said end plates, the said end plates being provided with a series of apertures for the purpose described, and pockets held on said cross-bars adjacent to the end plates, as set forth.

5. A shuttle-guard, comprising end plates adapted for pivotal connection with a hand-roll, cross-bars held on said end plates, a top cross-bar supported by the other bars, and pockets formed of flexible material and held on said cross-bars near the ends thereof, the pockets extending inwardly toward the reel, as set forth.

6. A shuttle-guard, comprising end plates pivoted to a hand-roll, cross-bars secured to the end plates, a top cross-bar, means for supporting the top cross-bar from the other cross-bars, and links connecting the end plates with the loom-frame, as set forth.

7. A shuttle-guard, comprising end plates pivoted to a hand-roll, cross-bars held on said end plates, and supporting a top cross-bar, and pockets held on said cross-bars and formed of cushion bands through which extend the cross-bars, as set forth.

8. A shuttle-guard comprising end plates pivoted to a hand-roll, cross-bars rigidly connecting the end plates, a top cross-bar supported from the other cross-bars, and arranged approximately in alignment with the pivots connecting the end plates to the hand-roll, and extension-links connecting the end plates with the loom-frame, as set forth.

9. A shuttle-guard, comprising end plates pivoted to a hand-roll, cross-bars held on said end plates, and cushioning-links connecting the end plates with the loom-frame, as set forth.

696,837. AUTOMATIC SHUT-OFF FOR GAS-LINER. JAMES R. LAMM and WILLIAM R. McFARLANE, Trenton, Pa. Filed Dec. 27, 1901. Serial No. 57,457. (No model.)

Claim.—1. The combination with a casing having an upper and a lower gas-chamber formed therein with a partition secured in the lower gas-chamber and ports formed in the upper face of the lower gas-chamber, one of said ports being on one side of the partition and the other of said ports on the other side thereof, a third port formed in the upper face of the lower gas-chamber, a lever pivotedly mounted in the upper gas-chamber, a valve carried on one end thereof for closing the last-named port leading into the lower gas-chamber, and a valve of greater size than the first-named valve carried on the other end of said lever and adapted to close both of said first-named ports formed in the upper face of the lower gas-chamber, the gas entering one of the first-named ports on the one side of the partition and supporting the valve of greater size and flowing through the other of said ports formed on the other side of the partition, substantially as described.

2. In a device of the character described, the combination with the casing having an upper and a lower gas-chamber, the ports formed on each side of the partition formed in the lower gas-chamber, and a third port formed in the upper face of the lower gas-chamber, of a pair of valves movable in unison mounted within the upper gas-chamber, one of said valves closing the last-named port and the other of said valves closing the ports on each side of said partition, the gas entering through the port on one side of the partition raising the valve and supporting the same and flowing through the other of the said ports on the other side of the partition, substantially as described.

696,838. DRAFTSMAN'S INSTRUMENT. BEN. C. LAMMERS, Pittsburgh, Pa. Filed Apr. 2, 1901. Serial No. 54,120. (No model.)

Claim.—1. A drawing instrument, comprising a transparent or translucent rectangular plate having on one of its surfaces longitudinal and transverse scales and reversed characters for said scales and provided approximately at its center with a trapezoidal-shaped block, as set forth.

2. A drawing instrument, comprising a transparent or translucent rectangular plate having on one of its surfaces a longitudinal scale along one edge, a transverse scale spaced from one edge and reverse characters for said scales, and provided approximately at its center with a trapezoidal-shaped block, as set forth.

3. A drawing instrument, consisting of a rectangular plate having longitudinal and transverse scales and lines radiating from two or more corners of the plate and intersecting each other.

4. A drawing instrument, consisting of a rectangular plate having a longitudinal scale and a transverse scale extending from the first-named scale at each point as to divide the rectangle into a square and a smaller rectangle and lines radiating from one of the corners of said square.

5. A drawing instrument consisting of a rectangular plate having a longitudinal scale and a transverse scale extending from the first-named scale at each point as to divide the rectangle into a square and a smaller rectangle, and provided with a block projecting from the surface of the plate and having its edges at an angle to those of the plate.

6. A drawing instrument consisting of a plate having lines radiating from two or more of its corners, and a block projecting from the plate and filling the quadrilateral formed by the intersection of four of said radiating lines.

7. A drawing instrument consisting of a plate, an approximately central block projecting therefrom with its edges at an angle to those of the plate, and additional blocks projecting from the same face of the plate and having two of their edges in alignment with the corresponding edges of the central block.

8. A drawing instrument, comprising a transparent or translucent rectangular plate having a longitudinal scale along one edge, a transverse scale spaced from one edge, a block secured to the plate approximately at its center and having its edges at an angle to the edges of the plate, and blocks secured to the plate near two corners, said blocks having two of their edges in alignment with the corresponding edges of the central block.

696,839. TEMPER-CREW CLAMP. PATRICK H. MACK, Bradford, Pa., assignor to the GE. WALL Supply Company, Pittsburgh, Pa., a Corporation of Pennsylvania. Filed Jan. 31, 1901. Serial No. 46,464. (No model.)

Claim.—1. A reape-clamp for temper-curves, comprising a plurality of longitudinally-separable clamp-sections having a sinuous reape-clamp therein made up of a series of reverse and equal curves oppositely placed in the coating clamp-sections, substantially as and for the purposes specified.

2. A reape-clamp for temper-curves, comprising a plurality of longitudinally-separable clamp-sections having an outer shell and a bushing, the bushings of the clamp-sections provided with sinuous reape-clamps made up of a series of reverse and equal curves oppositely placed in the coating clamp-sections, substantially as and for the purposes specified.

3. The combination with a temper-curve, of a reape-clamp comprising longitudinally-separable sections, provided with a sinuous reape-clamp therein, said reape-clamp having a plurality of equal and reverse curves oppositely placed in the coating clamp-sections, flexible connections between the clamp-sections and the crivrel-bar of the temper-curve, and means for confining the coating clamp-sections, substantially as and for the purposes specified.

696,840. PROCESS OF MAKING REPAIRED FABRIC. DAVID MARSHALL, Norfolk, Va., assignor to one-half to England Margolian, Norfolk, Va. Filed Nov. 2, 1901. Serial No. 51,572. (No specimens.)

Claim.—The method of repairing fabrics which have state or cuts produced therein inside of their margins or edges, which method consists first in extending the state or cuts from each and completely out to the adjacent margins of the fabric, and then in connecting together the matching ends of the threads of the fabric which have been covered.

696,841. SEPARATING AND BOLLING MACHINE. DANIEL W. MARSH, Indianapolis, Ind., assignor to North & Harrison Company, Indianapolis, Ind., a Corporation of Indiana. Filed Sept. 24, 1901. Serial No. 70,002. (No model.)

Claim.—1. The combination, in a separating and bolling machine, of a series of doves having corner-blocks formed of cast-iron wood slightly longer than the width of the dove-walls and arranged to rest upon each other when assembled thus forming practically continuous parts from the top to the bottom of the set of doves, said doves being each provided with elastic compressible packing-strips filling the interstices between the doves when assembled and rendering the assembled structure substantially air and dust tight at the sides, substantially as shown and described.

2. The combination, in a separating and bolling machine, with the frame or shell, of a series of doves mounted therein each dove having inner and outer walls arranged near each other at sides thereof, the space between the inner and outer walls forming passage-ways for the discharge of the stock being treated, said doves being equal in length and width and reversible in position whereby passage-ways at any of the various

edges and of a length equal to the thickness of any desired number of clove may be provided, substantially as set forth.

3. The combination, in a separating and bolting machine, of a series of clove of equal length and width, each of said clove having double walls along certain of their sides, and each clove being shiftable in respect to the others, whereby passage-ways of any of the various sizes, and within the clove structure, may be variably provided, substantially as set forth.

4. The combination, in a separating and bolting machine, of the frame or shell, and a series of clove mounted therein, said clove having double walls with passage-ways between, and certain of said clove having turn-out-shelves whereby the stock may be discharged either through the passage-ways in the clove structure or out into passage-ways in the frame or shell of the machine, substantially as and for the purposes set forth.

696,883. APPARATUS FOR STORING AND REMOVING RUBBER. SAMUEL HANSEN, Berlin, Germany. Filed Nov. 7, 1901. Serial No. 81,817. (No model.)

Claim.—1. The combination of a dust-bin, a rack suspended in said dust-bin, a box-like casing in the rack, a frame pivotally connected with the bin and having a depending funnel portion arranged to normally fit snugly within the upper end of said box-like casing and means for positively holding said frame in its normal position.

2. The combination of a dust-bin, a rack suspended in said dust-bin, a box-like casing in the rack, a frame pivotally connected with the bin and having a depending funnel portion arranged to normally fit snugly within the upper end of said box-like casing, a door for said bin, and means operative with the door for positively holding said frame in its normal position.

696,888. TYPE-WRITER. CHARLES E. MAXWELL, Wellington, N.Z. Filed Jan. 14, 1901. Serial No. 43,908. (No model.)

Claim.—1. In a type-writer, a type-wheel having on its exterior a plurality of type cases, type-wheel vibrating and rotating mechanism,

and means independent therefrom to rock said type-wheel about an axis transverse to the axis about which it rotates to bring either type case into operative position.

2. In a type-writer, a rotary type-wheel having on its exterior type cases at different angles to its axis of rotation, key mechanism to change the direction of the axis of rotation of said type-wheel to bring either type case into operative position, and type-wheel-vibrating mechanism independent of said key mechanism.

3. In a type-writer, a type-wheel having a plurality of type cases at different angles to its axis of rotation, a series of characters on each of said type cases, the series on different cases being different, a series of key-levers, means independent from the key-levers to bring either type case into operative position, and means operated by said key-levers to rotate the type-wheel through different angles to bring any desired character into operative position and to vibrate said type-wheel.

4. In a type-writer, a type-wheel having a plurality of type cases at different angles to its axis of rotation, one of said type cases bearing the small letters, another having the capital letters thereon, and another having figures or other characters, means to change the direction of the axis of rotation to bring either type case into operative position, and type-wheel rotating and vibrating mechanism.

5. In a type-writer, a type-wheel having on its exterior a plurality of type cases at different angles to its axis of rotation, one of said type cases having small letters thereon, another of said type cases having capital letters, and another of said type cases having figures or characters, key mechanism to change the direction of the axis of rotation of said type-wheel to bring either type case into operative position, and type-wheel-vibrating mechanism independent of said key mechanism.

6. In a type-writer, a type-wheel having a plurality of type cases at different angles to its axis, type-wheel-vibrating mechanism, and means independent therefrom to bring either type case into operative position.

7. In a type-writer, a type-wheel having a central, cylindrical type case, and at either side thereof a conical type case, and type-wheel-vibrating mechanism.

8. In a type-writer, a rotary type-wheel having a central, cylindrical surface, and a conical surface, each of said surfaces having letters or characters thereon, means to bring either of said surfaces into operative position, and type-wheel-vibrating mechanism.

9. In a type-writer, a rotary type-wheel having a central, cylindrical type-surface, and a conical type-surface, key mechanism to bring either type-surface into operative position, and type-wheel-vibrating mechanism.

10. In a type-writer, a rotary type-wheel having a central cylindrical type-surface, and at either side thereof a conical type-surface, means to swing said type-wheel to bring either type-surface into operative position, and type-wheel rotating and vibrating mechanism.

11. In a type-writer, a vibrating rotary type-wheel having a central, cylindrical type-surface, and at either side thereof a conical type-surface, means to swing said type-wheel about a transverse axis to bring either type-surface into operative position, and type-wheel rotating and vibrating mechanism.

12. In a type-writer, a vibrating rotary type-wheel having a central, cylindrical type-surface, and at either side thereof a conical type-surface, key-lever mechanism to swing the said type-wheel about a transverse axis to bring either type-surface into operative position, and type-wheel vibrating and rotating mechanism independent therefrom.

13. In a type-writer, a vibrating arm, means carried thereby to support a type-wheel for turning movement in two directions, key mechanism for turning the said type-wheel about its axis and vibrating said arm to bring the said wheel in contact with the paper, and independent key mechanism to change the direction of the axis of the type-wheel relative to the vibrating arm.

14. In a type-writer, a rotary type-wheel having a plurality of type cases at different angles to its axis, a shaft upon which said type-wheel rotates, a frame supporting said shaft, said frame being pivotally mounted upon an axis transverse to the axis of the type-wheel, key mechanism for controlling the frame, and type-wheel rotating and vibrating mechanism.

15. In a type-writer, a type-wheel having a plurality of type cases at different angles to the axis of said wheel, a yoke carrying a spindle on which said type-wheel rotates, said yoke being pivotally mounted on an axis transverse to the axis of the type-wheel, a key-lever connected to said yoke, whereby the same may be turned to bring either type case into operative position, and type-wheel-vibrating mechanism.

16. In a type-writer, a rotatable type-wheel having a plurality of type cases at different angles to its axis, a yoke having a spindle on which said type-wheel rotates, said yoke being pivotally mounted on an axis transverse to the axis of the type-wheel, a key-lever, connections between the same and the yoke, a stop limiting the movement of said key-lever, a supplemental key-lever pivotally mounted on the first-mentioned key-lever, a stop for the supplemental key-lever, said stops being of different heights, whereby the depression of the main key-lever and supplemental key-lever

operates to bring different type-cases into operative position, combined with type-wheel-vibrating mechanism.

17. In a book type-writer, a base, a carriage slidably supported thereon for movement longitudinally thereof, and printing mechanism slidably supported on said carriage for movement transversely of said base, said printing mechanism including a vibrating arm, a type-wheel pivotally supported thereon for movement about both a longitudinal and transverse axis, means to turn said wheel about its transverse axis, and type-wheel-vibrating mechanism.

18. In a type-writer, a vibrating arm, a type-wheel supported thereby for movement about both a longitudinal and transverse axis, a pinion on said arm, connections between said pinion and type-wheel, said connections including a universal joint, key-lever mechanism for rotating the pinion and vibrating the arm, and means to turn the type-wheel on its transverse axis.

19. In a type-writer, a vibrating arm, a type-wheel supported thereby for movement about both a longitudinal and transverse axis, a pinion on said arm, a slotted arm having pivotal connection with the pinion, a pin on said type-wheel engaging said slot, means for rotating the pinion, to thereby rotate the type-wheel and vibrating mechanism for the arm, and means to swing the type-wheel on its transverse axis.

20. In a book type-writer, a base, printing mechanism movable both longitudinally and transversely of said base, and printing mechanism comprising a rotary type-wheel having a plurality of type cases at different angles to its axis, means to bring any type case into operative position, and type-wheel-vibrating mechanism.

21. In a book type-writer, a base, a carriage slidably mounted thereon, printing mechanism supported on said carriage, said printing mechanism comprising a rotatable type-wheel having a plurality of type cases at different angles to its axis, means to bring any type case into operative position, key-levers, means operated thereby to vibrate the type-wheel, combined with mechanism to advance the printing mechanism to form spaces between letters, said mechanism comprising a rack fixed to the carriage and a reciprocating pawl on the printing-mechanism frame, and means common to all the key-levers to reciprocate the pawl.

22. In a book type-writer, a type-wheel having a plurality of type cases at different angles to its axis, means to normally hold one of said type cases in operative position, key-lever mechanism to bring either of the type cases into operative position, and type-wheel-vibrating mechanism.

23. In a book type-writer, a base, a carriage slidably supported thereon for movement longitudinally thereof, and printing mechanism slidably supported on the carriage for movement transversely of said base, said printing mechanism including a rotatable type-wheel having on its surface a plurality of type cases, type-wheel rotating and vibrating mechanism, and means independent therefrom to rock said type-wheel about an axis transverse to the axis about which it rotates to bring either type case into operative position.

696,884. MILK-MODIFYING GAG. JAMES A. MITCHELL, New York, N. Y. Filed Sept. 28, 1901. Serial No. 76,171. (No model.)

Claim.—1. As an article of manufacture, a milk-modifying gag comprising a strip of sheet material bent twice at right angles, the bent portions being spaced under a distance commensurate with the size of a milk-bottle, for the purpose of embracing the exterior of said bottle, and

provided with graduated scales parallel with the general direction of said bottle.

2. As an article of manufacture, a milk-modifying gag, comprising a strip of sheet material bent twice at right angles so as to partially embrace a bottle by engaging one of its sides and provided with sharp corners curved slightly inward for the purpose of clamping the bottom and two external sides thereof, a plurality of graduated scales arranged parallel with each other, and a plurality of peep-holes adjacent to said scales.

3. As an article of manufacture, a milk-modifying gag, comprising a strip of sheet material bent twice at right angles so as to embrace a bottle by engaging the bottom and two external sides thereof and provided with sharp corners curved slightly inward, and also provided with a plurality of peep-holes arranged in parallel longitudinal rows and with graduations for measuring various depths of milk, lime-water and boiled water in said bottle.

4. As an article of manufacture, a milk-modifying gag, comprising a longitudinal member of thin spring metal bent twice at right angles and provided with curved corners for clamping a bottle, and also provided with three exterior faces, one of said faces having a plurality of parallel graduated scales and parallel rows of peep-holes adjacent to said scales, and the other two of said faces being provided with material tabs.

696,885. MINIATURE THEATER. ARTHUR L. MCCORMICK, Port Huron, Mich. Filed Aug. 17, 1901. Serial No. 72,778. (No model.)

Claim.—1. A miniature theater substantially as described having a stage, figures or scenic objects movable from a point above the stage when in play to a point below the upper surface of the stage when out of play and means for automatically operating the said figures or objects substantially as set forth.

2. A miniature theater having a slotted stage, movable scenic objects arranged to be projected through said slot from a point above the stage when in play to a point below the upper surface of the stage when out of play, and means for automatically operating said objects substantially as set forth.

3. A miniature theater having automatically-operating devices by which to shift the scene, and a curtain arranged for operation in connection with such devices whereby the scene will be shifted when the curtain is drawn substantially as set forth.

4. In a miniature theater the combination of the scenic objects, the keys or levers for supporting and operating the same and the drum having pins or projections for operating said keys or levers, the levers terminating alongside the drum and operating in a direction tangentially to the drum at their ends adjacent thereto, whereby the movements of the levers will not be limited by coming in contact with the drum substantially as set forth.

5. In a miniature theater the combination of a stage having slot, the scenic objects movable through said slot to points above and below the upper surface of the stage, the keys or levers for operating said objects, and the drum having pins or projections by which to operate said keys or levers, substantially as set forth.

6. The combination in a miniature theater, of the stage, the scenic objects, the keys or levers carrying the same, the drum having pins or projections for operating the keys or levers and the operating mechanism having step-by-step devices for moving the pins-drum, substantially as set forth.

7. A theater substantially as described, comprising a movable con-

tain, movable scenic objects and automatically-operating devices arranged to shift the scenic objects when the curtain is down and the stage is not in view, substantially as set forth.

8. A miniature theater substantially as described comprising the movable scenic objects, the movable curtain, a movable indicator or announcing device, and the operating mechanism connected with said indicator, curtain, and scenic objects and arranged to shift the scenic objects when the curtain is down and the stage is not in view, substantially as described.

9. In a miniature theater the combination with the curtain, of a shaft in connection therewith, a pinion having an arm provided with a cord wound on said shaft, and the operating devices having a mutilated gear meshing with the said pinion, substantially as set forth.

10. The combination with a miniature theater of the movable scenic objects, the keys supporting the same, the drum having pins or projections engaging said keys, said drum being provided with a ratchet-wheel, a rocking arm having a pawl engaging said ratchet-wheel, the operating devices having a crank and a pinion connecting said crank with the rocking arm, and a mutilated gear, and the pinion having an arm, the curtain, the shaft in connection with said curtain, and the cord connecting said shaft with the arm of the pinion, substantially as set forth.

11. A theater having a stage, a curtain which may be adjusted to expose or hide the stage and operating means for shifting the curtain and moving the scenic objects and so arranged relatively to the curtain and scenic objects that the scenic objects will be shifted when the curtain is down, substantially as set forth.

12. A theater substantially as described, having a stage, figures or scenic objects movable into and out of position for exposure in connection with said stage, together with automatically-operating devices by which said figures or objects may be moved into view or entirely out of view with respect to the upper surface of the stage, substantially as set forth.

696,886. METHOD OF DESTROYING STUMPS OF TREES. JAMES J. R. McLELLAN, Groesbeck, Tex. Filed Nov. 12, 1901. Serial No. 51,354. (No model.)

Claim.—The herein-described method of destroying the stumps of trees consisting of applying a compound of saltpeter, soda and salt to the stump below the earth's surface, and then packing a protective coating around and upon the said stump to prevent removal of the compound substantially as herein set forth.

696,887. RAILWAY-TRUCK SPECIAL. THOMAS J. McTIGHER, New York, N. Y. Filed Nov. 4, 1901. Serial No. 51,078. (No model.)

Claim.—1. In a railway-truck special, a rail of mild steel having one or more of its local wearing-surfaces integrally modified into a hard steel or steel alloy capable of being hardened.

2. In a railway-truck special a rail of low-carbon steel substantially incapable of hardening, having one or more of its local wearing-surfaces integrally modified into high-carbon steel capable of hardening and tempering.

3. A railway-truck special composed partly or wholly of rolled railway-rails of low-carbon steel having one or more of their local wearing-surfaces integrally modified into high or hard steel.

4. A railway-truck special composed partly or wholly of rolled railway-rails of low-carbon steel having one or more of their wearing-surfaces integrally supercarburized.

5. A railway-truck having its point formed by two converging railway-rails of low-carbon steel, the tops of either or both said rails being locally modified into hard steel at and near the point.

6. A railway-truck having its wings formed of low-carbon-steel railway-rails which are integrally modified into hard steel locally adjacent to the intersection-point of the frog.

696,888. CONCRETE-ARCH CONSTRUCTION. WALTER C. PARKLEY, Cleveland, Ohio. Filed June 4, 1901. Serial No. 52,080. (No model.)

Claim.—1. A concrete arch having embedded therein metal bars which extend continuously through all the regions of tension in intrados or extrados of the arch, and other bars which extend through part only of the regions of tension in either intrados or extrados, substantially as described.

2. A concrete arch having embedded therein metal bars which extend continuously through all the regions of tension in intrados or extrados of the arch, and other bars alternating therewith, which extend through part only of the regions of tension in either intrados or extrados, substantially as described.

3. A concrete arch having metal bars embedded therein, both in intrados and extrados, at the regions of tension and extending continuously through the regions of tension and sufficiently into the abutments to obtain a secure anchorage, the bars in the extrados being opposite the spaces between those in the intrados.

4. A concrete arch having embedded therein metal bars which pass continuously through all the regions of tension in both intrados and extrados and other bars extending through part of the tensional regions only and far enough beyond to give secure anchorage.

5. A concrete arch having embedded therein metal bars which pass continuously through the regions of tension in both intrados and extrados and other bars alternating therewith and extending through part only of the tensional regions and far enough beyond to give secure anchorage.

6. A concrete arch having embedded therein metal bars which pass continuously through the regions of tension in both intrados and extrados and other bars which extend through a single tensional region and far enough beyond to give secure anchorage, the bars of one set being opposite the interspaces between the bars of the other set.

696,889. THILL-COUPLING. ADRIANUS PARR, Coburn, N. Y. Filed Oct. 7, 1901. Serial No. 77,347. (No model.)

Claim.—1. In a thill coupling, the combination of a conical sleeve, a cap-nut and means securing said cap-nut and sleeve together in reversible relation to each other, devices adapted to lock the said cap-nut yieldingly upon the sleeve against accidental rotation with respect to the said sleeve, a thill-tree having a head bored apically, an axle-clip, and means for clamping the whole together and for preventing rotation of the sleeve relative to the axle-clip, substantially as described.

2. In a thill-coupling, a cap-nut having an exterior threaded portion and a central bore, a part of the bore being threaded and a part toward the bottom of the bore smooth and constituting an oil-chamber, and the cap-nut being provided with a spring-pin operating parallel with the axis of the nut, substantially as described.

3. In a thill-coupling, the combination of a cap-nut having an exterior threaded portion, a central threaded bore and a spring-pin operating parallel with the axis of the nut, a hardened sleeve having a head projecting like a collar from one end of the sleeve and the outer face of the said head being provided with a circular series of depressions adapted to receive the point of the said spring-pin, and an annular lock-nut having an interior threaded portion engaging the exterior threads of the cap-nut and a central orifice controlling the sleeve, the bottom of the lock-nut meeting the rear of the head and holding the sleeve and cap-nut together in reversible relation to each other, substantially as described.

4. In a thill-coupling, the combination of a cap-nut having an exterior threaded portion, a central threaded bore and a spring-pin operating parallel with the axis of the nut, a hardened conical sleeve having a head projecting like a collar from one end of the sleeve and the outer face of the said head being provided with a circular series of depressions adapted to receive the point of the said spring-pin, an annular lock-nut having an interior threaded portion engaging the threads of the cap-nut and a central orifice controlling the sleeve, the bottom of the lock-nut meeting the rear of the head and holding the sleeve and cap-nut together in reversible relation to each other, an axle-clip having one end provided with a circular orifice fitting the sleeve and a second end pivoted by a square hole, and a clamping-bolt having a squared shank and threaded end, the shank fitting the square hole in the clip and passing of the sleeve thereby permitting the cap-nut only to be turned, and the threaded end of the bolt engaging the central threads of the cap-nut and clamping the whole together, substantially as described.

696,840. FURNACE OF STEAM-BOILERS. ADOLPH FRANKOWITZ and STEPHEN F. JOHNSON, London, England. Filed Aug. 12, 1901. Serial No. 72,548. (No model.)

Claim.—1. In a steam-boiler furnace, the combination of a main fire-grate, and a secondary grate adjacent thereto, comprising a plate covered with asbestos or like material; of means for directing a blast of steam against the under side of said secondary grate for removing deposits therefrom, substantially as described.

2. In a steam-boiler furnace, the combination of a main fire-grate, and a secondary grate adjacent thereto, comprising a plate covered with asbestos or like material; of a funnel-shaped nozzle located beneath said secondary grate adapted to direct a blast against the under side of said secondary grate for removing deposits therefrom, and means connected with the boiler of said furnace for supplying steam to said nozzle, substantially as described.

696,841. CULM DRINE AND SEPARATOR. JAMES W. PERRY, Shamokin, Pa. Filed Apr. 12, 1901. Serial No. 56,416. (No model.)

Claim.—1. In an apparatus for separating and drying culm, the combination of an inclosing casing, one or more screens in the upper portion of the casing, feeding and discharge chutes cooperating with said screens, a fire-box in the lower portion of the casing, a hopper above the fire-box, a heat-conducting pipe leading from the fire-box to the upper portion of the casing adjacent to the screens, and means for conducting refuse material falling through the screens to said hopper, substantially as described.

2. In an apparatus for separating and drying culm, the combination of an inclosing casing having an outlet for refuse, a fire-box in the lower portion of the casing, one or more shaking-screens in the upper portion of the casing, a heat-conducting pipe leading from the fire-box to a point adjacent to the screens, a feed-chute for supplying culm to the screens, a

discharge-chute to receive the culm therefrom, and means for conducting a portion of the refuse matter falling from the screens to the fire-box and the remainder to the refuse-outlet, substantially as described.

3. In an apparatus for separating and drying culm, the combination of an inclosing casing, a fire-box in the base of the casing, a smoke-stack, a direct flue leading from the fire-box to the smoke-stack, a second flue leading from the upper portion of the casing to the smoke-stack, a damper controlling the direct flue, a hopper above the fire-box, shaking-screens in the upper portion of the casing, feed-discharge chutes cooperating with the screens, a refuse-outlet, and converging plates inclining downwardly to direct a portion of the refuse to the hopper and a portion to said outlet, substantially as described.

696,842. GARMENT-SUPPORTER. GEORGE H. PHELPS, Boston, Mass., assignor to George Frost Company, Boston, Mass., a Corporation of Massachusetts. Filed Dec. 15, 1900. Serial No. 38,965. (No model.)

Claim.—1. A garment-supporter comprising a clamp, a suspending-cord attached thereto and a band to which the cord is connected and which is formed to have a short stretch and elasticity sufficient only to cause the garter to cling to the leg without binding or producing an objectionable tension, and which has an inner surface of rougher or coarser material than the outer surface.

2. A garter comprising a clamp, a suspending-cord attached thereto, and a band composed of webbing having its outer face formed of threads of one material, its opposite face formed of threads of rougher or coarser material which are bound to the threads forming the outer face, and elastic threads having a short stretch, interposed between the inner and outer fabrics, and having elasticity sufficient only to cause the garter to cling to the leg without binding or producing an objectionable tension.

696,843. PNEUMATIC-DESPATCH TERMINAL. FRANK C. PHILLIPS, London, England, assignor to the Lamson Consolidated Storage Service Company, Newark, N. J., a Corporation of New Jersey. Filed Dec. 12, 1900. Serial No. 740,174. (No model.)

Claim.—1. An upward-discharge terminal for pneumatic-despatch-tube system, comprising in combination a substantially conical

bular member to be secured at one end to the upper end of the receiving-tube and constituting the discharging element of the terminal, a short straight tubular member adapted to be secured to the upper end of the sending-tube directly beneath and within the curve of said semicircular member and constituting the sending element of the terminal, and an air-return-pipe section uniting said curved and straight tubular members laterally near their discharging and receiving ends respectively, the space bounded by and included within said parts being entirely open, whereby the sender is equally accessible from all sides of the terminal, substantially as described.

2. Is an upward-discharge terminal for pneumatic-dispatch-tube-system, a curved tubular member adapted to be secured to the upper end of the receiving-tube and having its downwardly-discharging end closed by a door or flap, a short straight tubular member adapted to be secured to the upper end of the sending-tube and located directly beneath and within the curve of the said first-named member and having its upper end closed by a suitable lid or door, and a pipe-section uniting said curved and straight tubular members laterally near their discharging and receiving ends respectively to permit the free circulation of the air-current through the terminal, all combined, substantially as set forth.

3. Is a pneumatic-dispatch apparatus, a terminal consisting of two members, means for holding said members together, an incoming tube attached to one member of said terminal, an outgoing tube in communication with the other member of said terminal and having its upper end open to the atmosphere, and valves for closing the outlet from said terminal and the inlet to said outgoing tube.

4. Is a pneumatic-dispatch apparatus, a terminal consisting of two members, means for holding said members together, an incoming tube attached to one member of said terminal, an outgoing tube in communication with the other member of said terminal and having its upper end open to the atmosphere, and spring-controlled valves adapted to automatically close the outlet from said terminal and the inlet to said outgoing tube.

5. Is a pneumatic-dispatch apparatus, a terminal consisting of two members, means for holding said members together, an incoming tube attached to one member of said terminal, an outgoing tube in communication with the other member of said terminal and located within the curved members of the terminal and having its upper end open to the atmosphere, and valves for closing the outlet from said terminal and the inlet to said outgoing tube.

696,844. SPIKE-DRAWING TOOL. JAMES E. RICE, Montreal, Canada. Filed Sept. 20, 1901. Serial No. 73,963. (No model.)

Claim.—1. A spike-drawing tool comprising a standard consisting of a single vertical plate adapted to rest upon the top of the rail and having a hooked lower end to clip the head of said rail; a segmental drum having its periphery cut away midway of its axial length to straddle said plate; means for fastening said segmental drum to the upper end of said plate concentrically of said drum; a lever-arm formed in one with and

projecting radially from said drum in line with one end of the cut-away portion of said drum; a pair of flexible lengths one on each side of said lever and carried by and depending from said lever at the point at which it abuts said segmental drum; and a pair of pivotally-connected gripping-jaws hung from the lower ends of said flexible lengths, substantially as described and for the purpose set forth.

2. A spike-drawing tool comprising a standard consisting of a single vertical plate adapted to rest upon the top of the rail and having a hooked lower end to clip the head of said rail; a segmental drum having its periphery cut away midway of its axial length to straddle said plate; a pair of flanges one on each side of said plate and integral with the interior of said segmental drum and interposed to the upper end of said plate concentrically of said drum; a lever-arm formed in one with and projecting radially from said drum in line with one end of the cut-away portion of said drum; a pair of flexible lengths one on each side of said lever and carried by and depending from said lever at the point at which it abuts said segmental drum; and a pair of pivotally-connected gripping-jaws hung from the lower ends of said flexible lengths, substantially as described and for the purpose set forth.

696,845. STOCK. EDWARD J. RYBEN, Jackson, Mich. Filed Dec. 26, 1901. Serial No. 57,757. (No model.)

Claim.—A stock, in combination with a button-hole-strip secured to the inner face of the stock at a point above its lower edge and having one end extending at right angles from the body portion and secured to the stock at a distance from one of its ends, whereby is produced a longitudinal and a vertical flap, said strip being provided with button-holes, substantially as set forth.

696,846. TRUNK. SIMON E. V. SEWARD, Petersburg, Va., assignor to Seward Trunk and Bag Company, Petersburg, Va., a Corporation of Virginia. Filed Dec. 26, 1901. Serial No. 57,955. (No model.)

Claim.—1. The combination with a trunk, of a lid therefor, a tray pivotally secured to said lid, and a track having inclined and horizontal portions upon an end face within the trunk and extending from the front of the trunk less than one-half the depth thereof to support the front portion of said tray, substantially as specified.

2. The combination with a trunk, of a lid therefor, a tray pivotally secured to said lid, and a track for said tray having an inclined front portion and a horizontal rear portion composed of parallel flanges and an intermediate bearing-face at a right angle thereto; substantially as specified.

3. The combination with a trunk, of a lid therefor, a tray pivotally connected with said lid sufficiently forward from the rear side thereof to enable the tray to be lifted over the rear side of the trunk when the lid is elevated, and an inclined track for the forward portion of said tray extending less than one-half the depth of the trunk; substantially as specified.

4. In a trunk, a tray-track composed of a blank having parallel flanges at its edge, and an intermediate bearing-face at a right angle to said flanges; substantially as specified.

5. In a trunk, a journaling-plate having a securing-flange at one side and end thereof, and an embossed portion disposed in a parallel plane to said flange and provided with a free edge having an open slot therein; substantially as specified.

696,847. VACUUM AND WATER RELIEF VALVE APPARATUS FOR LOCOMOTIVES. ALEXANDER BRUNNEN, London, England. Filed Sept. 30, 1901. Serial No. 77,111. (No model.)

Claim.—1. Relief valve apparatus for locomotive and other like engines, comprising a valve-casing having a tubular branch the interior of which forms a vacuum-relief passage, a steam-supply chamber adapted to be connected to a steam-generator, a steam-passage extending from said steam-chamber to said vacuum-relief passage and terminating in a nozzle projecting into said vacuum-relief passage, and an air-inlet passage leading into said vacuum-relief passage and arranged opposite to said steam-inlet passage, a steam-valve located in said steam-chamber, provided with a stem extending through said steam-passage, and adapted to normally close said passage, and an inwardly-opening air-valve that normally closes said air-passage and is provided with an inwardly-extending stem or projection arranged to abut against the stem of said steam-valve and open the same when said air-valve opens, substantially as described for the purpose specified.

2. Relief valve apparatus for locomotive and other like engines, comprising a valve-casing having a vacuum-relief passage adapted to be placed in communication with the steam chest or cylinder or cylinders of an engine of the kind referred to, oppositely-arranged steam and air inlet passages adapted to communicate with said vacuum-relief passage, and a water-relief-valve chamber having one end in communication with the steam-inlet passage, its other end adapted to be placed in communication with an engine-cylinder, and an intermediate part in connection with a water-exit passage, oppositely-arranged steam and air valves controlling said steam and air inlet passages respectively, said steam-valve having an inwardly-extending stem, and said air-valve being made of much larger area than said steam-valve and having a projection or stem adapted to abut against said steam-valve and open the same, and a water-relief valve arranged to work in said chamber and control the exit of water through said water-exit passage, substantially as described for the purpose specified.

3. Relief valve apparatus for locomotive and other like engines, comprising a valve-casing having a tubular branch the interior of which forms a vacuum-relief passage, a steam-supply chamber adapted to be connected to a steam-generator, a steam-passage extending from said steam-chamber

to said vacuum-relief passage, an air-inlet passage leading into said vacuum-relief passage and arranged opposite to said steam-inlet passage, water-exit passages the outer ends of which are adapted to be connected to an engine cylinder or cylinders, cylindrical valve-chambers each having one end in permanent communication with said steam-chamber and its other end adapted to communicate with one of said water-exit passages and having its wall between its ends formed with a water-exit port or passage, a steam-valve located in said steam-chamber, provided with a stem extending through said steam-passage, and adapted to normally close said passage, an inwardly-opening air-valve that normally closes said air-passage and is provided with an inwardly-extending stem or projection arranged to abut against the stem of said steam-valve and open the same when said air-valve opens, and water-relief valves arranged within said cylindrical chambers and normally bearing against annular seats that surround the inner ends of said water-exit passages and the inner diameter of each of which is of less diameter than the corresponding water-relief valve, substantially as described for the purpose specified.

4. Relief valve apparatus for locomotive and other like engines, comprising a valve-casing *a* having a tubular branch *a'*, a steam-chamber *b* adapted to be connected to a steam-pipe, a steam-passage *c* extending from said steam-chamber, arranged at right angles to said tubular branch *a'*, and provided with a steam-delivery nozzle *d* arranged to deliver into said tubular branch, a stationary guide *e*, and an air-passage *f* through its lower part, a steam-valve *g* located in said steam-chamber and adapted to bear against an annular seat around the inlet end of said steam-passage *c*, a stem *h* attached to said valve and extending through said steam-passage and into said guide, a bush *i* fixed in said air-inlet passage *f*, and an air-inlet valve *j* adapted to seat itself against the annular inner end of said bush and provided with a projection *k* arranged to work in said guide and to abut against the adjacent end of said valve-stem when the air-valve opens, substantially as described for the purpose specified.

5. Relief valve apparatus for locomotive and other like engines, comprising a valve-casing *a* having a tubular branch *a'*, a steam-chamber *b* adapted to be connected to a steam-pipe, a steam-passage *c* extending from said steam-chamber, arranged at right angles to said tubular branch *a'*, and provided with a steam-delivery nozzle *d* arranged to deliver into said tubular branch, a stationary guide *e*, an air-passage *f* through its lower part, water-exit passages *g* the outer ends of which are adapted to be connected to pipes *h* and the inner ends of which are surrounded by annular valve-seats *i*, cylindrical water-relief-valve chambers *j* located above said valve-seats *i*, passages *k* connecting the upper ends of said chambers to said steam-chamber *b*, and a water-delivery outlet in communication with said chambers *j* through ports *l* located between the ends of said chambers, a steam-valve *m* adapted to control said steam-passage *c*, a stem *n* attached to said steam-valve, an air-valve *o* adapted to control said air-inlet passage *f* and provided with a projection *p*, and cylindrical water-relief valves *q* arranged to work in said chambers *j* and to normally bear against said seats *i*, substantially as described for the purpose specified.

696,848. LADDER-BRACK. CHARLES A. TRUITT, Chincoteague Island, Va. Filed Aug. 2, 1901. Serial No. 76,312. (No model.)

Claim.—1. An adjustable ladder-bracket comprising a platform-support provided at one end with a pair of hooks adapted to engage the rungs of the ladder, said hooks being connected to said support by horizontally-pivoted links, adapting said hooks to be placed at varying distances from each other on the rung, in combination with a diagonally-disposed brace adjustably connected at its upper end with the outer end of said support,

and similarly at its lower end with double hooks adapted to engage the ladder-rungs, substantially as set forth.

2. An adjustable ladder-bracket comprising a platform-support provided at one end with a pair of hooks adapted to engage the rungs of the ladder, said hooks being connected to said support by links pivoted to said support and said hooks, a rod or bar extending between said hooks and provided with steps or changes for holding said hooks at varying distances apart, in combination with a frame adjustably connected at its upper end with the outer end of said support and at its lower end with hooks adapted to engage the ladder-rungs, substantially as set forth.

3. In a ladder-bracket device of the character described, a platform-support consisting of an elongated bar provided at one end with means for adjustably engaging a supporting-brace, and at its opposite end with lateral extensions upon each side, links horizontally pivoted in such extensions, and hooks pivoted to the outer ends of said links, whereby said hooks are made adjustable at varying distances apart, substantially as set forth.

4. In a ladder-bracket device, a platform-support comprising an elongated bar adjustable at one end to a supporting-brace, and provided at its opposite end with lateral legs upon each side, links horizontally pivoted in each leg, hooks adapted to engage the rungs of the ladder horizontally pivoted in the outer ends of said links, and rods connecting said hooks and provided with spacing-changes whereby said hooks may be adjusted at varying distances apart, substantially as set forth.

696,849. REVERSING AND VARIABLE-SPEED GEARING.
HERBERT S. UNDERWOOD, Stamford, Conn., assignor to International Power Vehicle Company, Stamford, Conn., a Corporation of West Virginia. Filed Oct. 20, 1901. Serial No. 78,711. (No model.)

Claim.—1. In a friction-gearing, the combination with a driving crowned disk, of a rigidly-supported cross-shaft, and a pulley having a movement upon the said shaft and across the face of the said disk, from side to side thereof, substantially as described.

2. In a friction-gearing, the combination with a driving crowned disk, of a rigidly-supported cross-shaft, and a driven pulley mounted thereon and having a movement on the said shaft and across the said disk, from side to side thereof, the periphery of the said pulley being of yielding material whereby this movement is permitted, substantially as described.

3. The combination with a main shaft, of bearings therefor, a bracket projecting from the said bearings and having planed ends thereon, standard adjustably secured to the planed end of the bracket, a cross-shaft mounted in said standards, a driving-disk mounted on the end of the main shaft, and having a crowned face and a pulley movable upon the said

cross-shaft and across the face of the disk, from side to side thereof, substantially as described.

4. The combination with a main shaft, of bearings therefor, a bracket projecting from the said bearings and having planed ends thereon, and large adjustably secured to said ends, standard adjustably secured to the planed ends of the bracket, adjusting-screws taking into the large and bearing upon the said standards, a cross-shaft mounted in the said standards, a driving-disk mounted on the end of the main shaft, and having a crowned face and a pulley movable upon the said cross-shaft and across the face of the disk, from side to side thereof, substantially as described.

5. The combination with a main shaft, of bearings therefor, a bracket projecting from the said bearings, a driving-disk having a crowned face mounted on the end of the main shaft, a cross-shaft rigidly mounted in the bracket, a pulley, mounted on the cross-shaft to move thereon, and having a yielding face and provided with a groove, a collar mounted in the said groove in the pulley, and a lever pivoted to the said bracket and loosely connected to the said collar whereby the pulley may be shifted along the cross-shaft and across the face of the disk, from side to side thereof, substantially as described.

6. In a friction and clutch gearing, the combination with a driving crowned disk, having a central depression on its face, of a rigidly-supported cross-shaft, and a pulley having a movement across the face of the said disk from side to side thereof, substantially as described.

696,850. ANIMAL-POKE. ARTHUR ALTMAN, Grafting, Iowa. Filed Jan. 27, 1902. Serial No. 91,347. (No model.)

Claim.—1. The combination with a halter or head-harness; of a socket-plate secured to the lower end thereof and provided with an inwardly-projecting stud, a pole-bar having its lower end fitted in said socket and provided with a transversely-disposed recess engaged by the inwardly-projecting stud, whereby said bar is prevented from vertical displacement but is permitted a forward and rearward movement, a spring-rod having a longitudinal slot through which the upper end of the pole-bar projects, a pricking-point located in said casing and provided with a head at its outer end which is located within the path of movement of the pole-bar, and a spring arranged within said casing for forcing the pricking-point outwardly, substantially as specified.

2. The combination with a head-harness or halter; of jointed plates attached thereto and adapted to be arranged upon the upper surface of the neck of the animal, and the rear one of which is in close proximity to the shoulder of the animal, said plates being connected together by vertically-disposed rivets and the rearmost plate being provided with pricking teeth or points, substantially as set forth.

3. The combination with a head-harness or halter; of jointed plates attached thereto and adapted to be arranged upon the upper surface of the neck of the animal, and the rear one of which is in close proximity to the shoulder of the animal, said plates being connected together by vertically-disposed rivets and the rearmost plate being provided with pricking teeth or points, and a tackhead connected to the rearmost plate and adapted to pass around the neck of the animal, substantially in the manner described.

696,851. SEMI-AUTOMATIC GUN. LAURENCE V. REED, Paris, France. Filed June 20, 1901. Serial No. 68,282. (No model.)

Claim.—1. In a long-recoil semi-automatic gun, the combination with the gun-body and breech mechanism, of a spring under tension carried by the gun-body, and connected to said gun-body and said breech mechanism, and a lever and actuating-rod operated at any predetermined point of the recoil of the gun for actuating said breech mechanism against the action of said spring, substantially as described.

2. In a long-recoil semi-automatic gun, the combination with the gun-body and breech mechanism, of a spring under tension carried by

the gun-body and connected to said gun-body and said breech mechanism, and an actuating-rod carried by the gun and engaging the gun-mount at any predetermined point of the recoil of the gun for operating said breech mechanism against the action of said spring, substantially as described.

3. In a long-recoil semi-automatic gun, the combination with the gun-body and breech mechanism, of a spring under tension carried by the gun-body and connected to said gun-body and said breech mechanism, a rod carried by the gun and operated by engagement with the gun-mount at any predetermined point of the recoil of the gun for actuating said breech mechanism against the action of said spring, and independent means for holding the breech mechanism in the open position and for releasing the same, substantially as described.

4. In a long-recoil semi-automatic gun, the combination with the gun-mount, the gun-body and breech mechanism, of a spring under tension carried by the gun-body, and connected to said gun-body and said breech mechanism, an operating-lever, and an actuating-rod engaging a stop on the gun-mount at any predetermined point of the recoil, for actuating said breech mechanism against the action of said spring, means operated by said lever for throwing said rod out of engagement with the gun-mount when the breech is completely open, and independent means for holding said breech mechanism in the open position and for releasing the same to be automatically closed by said spring, substantially as described.

5. In a long-recoil semi-automatic gun, the combination with the gun-mount, the gun-body and breech mechanism, of a spring under tension carried by the gun-body, and connected to said gun-body and said breech mechanism, an operating-lever, and an actuating-rod engaging a stop on the gun-mount at any predetermined point of the recoil, for actuating said breech mechanism against the action of said spring, means operated by said lever for throwing said rod out of engagement with the gun-mount when the breech is completely open, and independent means for holding said breech mechanism in the open position and for releasing the same to be automatically closed by said spring, substantially as described.

6. In a long-recoil semi-automatic gun, the combination with the gun-mount, the gun-body and breech mechanism, of a spring under tension carried by the gun-body, and connected to said gun-body and said breech mechanism, an operating-lever, and an actuating-rod engaging a stop on the gun-mount at any predetermined point of the recoil, for actuating said breech mechanism against the action of said spring, and an extractor for holding said breech mechanism in the open position and for releasing the same to be automatically closed by said spring, substantially as described.

7. In a long-recoil semi-automatic gun, the combination with the gun-body and breech mechanism, of a spring under tension carried by the gun-body and connected to said gun-body and said breech mechanism, an actuating-rod carried by the gun and engaging the gun-mount at any predetermined point of the recoil of the gun for operating said breech mechanism against the action of said spring, and an extractor holding the breech mechanism in the open position and automatically releasing the same on the insertion of a cartridge, substantially as described.

8. In a long-recoil semi-automatic gun, the combination with the

gun-body and breech mechanism, of a spring under tension carried by the gun-body and connected to said gun-body and said breech mechanism, a rod carried by the gun and operated by engagement with the gun-mount at any predetermined point of the recoil of the gun for actuating said breech mechanism against the action of said spring, and then releasing said mechanism, and an extractor automatically holding the breech mechanism in the open position and automatically releasing the same, on the insertion of a cartridge, substantially as described.

9. In a long-recoil semi-automatic gun, the combination with the gun-body and breech-block, and a lever for operating said breech-block, having a downwardly-projecting arm, of a spring under tension carried by the gun-body and connected to said gun-body and to said lever, and a rod pivoted to the lower arm of said lever and operated by engagement with the gun-mount at any predetermined point of the recoil of the gun, for rocking said lever against the action of said spring and then moving said breech-block to the open position, substantially as described.

10. In a long-recoil semi-automatic gun, the combination with the gun-body and breech-block, and a lever for operating said breech-block, having a downwardly-projecting arm, of a spring under tension carried by the gun-body and connected to said gun-body and to said lever, a rod pivoted to the lower arm of said lever and operated by engagement with the gun-mount at any predetermined point of the recoil of the gun, for rocking said lever against the action of said spring, and then moving said breech-block to the open position, and independent means for holding the breech-block in the open position and for releasing the same when desired, substantially as described.

11. In a long-recoil semi-automatic gun, the combination with the gun-mount, the gun-body and breech-block, and a lever for operating said breech-block, having a downwardly-projecting arm, of a spring under tension carried by the gun-body and connected to said gun-body and to said lever, a rod pivoted to the lower arm of said lever and operated by engagement with the gun-mount at any predetermined point of the recoil of the gun, for rocking said lever against the action of said spring, and then moving said breech-block to the open position, and an extractor holding the breech-block in the open position and automatically releasing the same on the insertion of a cartridge, substantially as described.

12. In a long-recoil semi-automatic gun, the combination with the gun-mount, the gun-body and breech mechanism, of a spring under tension carried by the gun-body, and connected to said gun-body and said breech mechanism, an operating-lever, an actuating-rod engaging a stop on the gun-mount at any predetermined point of the recoil, for actuating said breech mechanism against the action of said spring, and means for throwing said rod out of engagement with the gun-mount when the breech is completely open, substantially as described.

13. In a long-recoil semi-automatic gun, the combination with the gun-mount, the gun-body and breech mechanism, of a spring under tension carried by the gun-body, and connected to said gun-body and said breech mechanism, an operating-lever, an actuating-rod engaging a stop on the gun-mount at any predetermined point of the recoil, for actuating said breech mechanism against the action of said spring, means operated by said lever for throwing said rod out of engagement with the gun-mount when the breech is completely open, and independent means for holding said breech mechanism in the open position and for releasing the same to be automatically closed by said spring, substantially as described.

14. In a long-recoil semi-automatic gun, the combination with the gun-mount, the gun-body and breech mechanism, of a spring under tension carried by the gun-body, and connected to said gun-body and said breech mechanism, an operating-lever, an actuating-rod engaging a stop on the gun-mount at any predetermined point of the recoil, for actuating said breech mechanism against the action of said spring, means operated by said lever for throwing said rod out of engagement with the gun-mount when the breech is completely open, and an extractor for holding said breech mechanism in the open position and for releasing the same to be automatically closed by said spring, substantially as described.

15. In a long-recoil semi-automatic gun, the combination with the gun-body and breech mechanism, of a spring under tension carried by the gun-body and connected to said gun-body and said breech mechanism, an actuating-rod carried by the gun and engaging the gun-mount at any predetermined point of the recoil of the gun for operating said breech mechanism against the action of said spring, means operated by said lever for throwing said rod out of engagement with the gun-mount when the breech is completely open, and an extractor holding the breech mechanism in the open position and automatically releasing the same on the insertion of a cartridge, substantially as described.

16. In a long-recoil semi-automatic gun, the combination with the gun-body and breech-block, and a lever for operating said breech-block, having a downwardly-projecting arm, of a spring under tension carried by the gun-body and connected to said gun-body and to said lever, a rod pivoted to the lower arm of said lever and operated by engagement with the gun-mount at any predetermined point of the recoil of the gun for

racking said lever against the action of said spring, and bearing-flange on said lower arm and on said rod to automatically trip the latter clear of engagement with said gun-mount when the breech is completely open.

17. In a long-recoil semi-automatic gun, the combination with the gun-body and breech-block, and a lever for operating said breech-block, having a downwardly-projecting arm, of a spring under tension carried by the gun-body and connected to said gun-body and to said lever, a rod pivoted to the lower arm of said lever and operated by engagement with the gun-mount at any predetermined point of the recoil of the gun, for rocking said lever against the action of said spring, and then moving said breech-block to the open position, bearing-flange on said lower arm and on said rod to automatically trip the latter clear of engagement with said gun-mount when the breech is completely open, and independent means for holding the breech-block in the open position and for releasing same when desired, substantially as described.

18. In a long-recoil semi-automatic gun, the combination with the gun-body and breech-block, and a lever for operating said breech-block, having a downwardly-projecting arm, of a spring under tension carried by the gun-body and connected to said gun-body and to said lever, a rod pivoted to the lower arm of said lever and operated by engagement with the gun-mount at any predetermined point of the recoil of the gun, for rocking said lever against the action of said spring, and then moving said breech-block to the open position, bearing-flange on said lower arm and on said rod to automatically trip the latter clear of engagement with said gun-mount when the breech is completely open, and an extractor holding the breech-block in the open position and automatically releasing the same on the insertion of a cartridge-case, substantially as described.

696,852. NAIL-HOLDING IMPLEMENT. FRANK BUCKA, Wai
Cham, Minn. Filed Apr. 16, 1901. Serial No. 98,105. (No model.)

Claim.—1. A nail-holding implement, comprising a stock, a hand-grip on the upper end of the stock, a head formed with radial grooves or channels secured on the lower end thereof, and spring-metal nail-gripping fingers attached to the stock and having their free ends passing through the channels or grooves in the said head.

2. A nail-holding implement, comprising a stock, a head on the lower end thereof provided on its sides with radial grooves or channels, and spring-metal nail-gripping fingers attached at one end to the stock and provided at their free ends with nail-gripping portions terminating in outwardly-deflecting extremities projecting beyond the head.

696,853. WARNING-MACHINE. FRANK BUCKA, Wai
Cham, Minn. Filed Sept. 28, 1901. Serial No. 76,957. (No model.)

Claim.—1. The combination with a washboard, of a wire frame comprising parallel rods connected together at their upper ends, means for securing the rods to the sides of the washboard-frame, a transverse rod loosely attached at its ends to said parallel rods, and a hand-rubber movably supported on said transverse rod.

2. The combination with a washboard, of a wire frame comprising parallel rods bent rearward at their upper ends and connected by a transverse wire rod, means for detachably connecting the rods to the frame comprising the upturned ends of the rods and catches at the top of the frame, transverse rods having loops at their ends through which the parallel rods extend, and a rubber having openings through which the transverse rods extend, and provided with a corrugated rubbing-surface.

696,854. LAMP-LIGHTER AND MATCH-EXTINGUISHER. WHITNEY R. GAIN and OLIVE R. GAIN, Port Jervis, N. Y. Filed June 9, 1900. Serial No. 19,226. (No model.)

Claim.—In an attachment for lamps, a lamp-casing, core located adjacent to an opening in said casing, a tube having one end projecting through the casing, the outer end of said tube being cut away at one side to permit the tube to lie close against the lamp-casing forming a guard for the opening, means for pivoting the tube to the core, a spring for holding the tube in its normal position and a match-erecting arm on the inside of the casing, in proximity to which the inner end of the tube extends.

696,855. FIRE-ESCAPE. WHITNEY R. GAIN and HAPLEIGH R. GAIN, Port Jervis, N. Y. Filed Aug. 26, 1901. Serial No. 72,319. (No model.)

Claim.—1. The improved fire-escape comprising a circular casing a shaft journaled concentrically therein, and provided with sprocket-wheel, and a radial arm which is tapered toward its outer end, a chain adapted to travel on the wheel, and a rectangular weight having a slot whose diameter is slightly greater than the widest portion of the sprocket-wheel, the weight being of such length that when traction is applied to the chain and the shaft rotated the weight is thrown into an inclined position and one of its outer corners engaged with the inner wall of the casing, as shown and described.

2. The combination, with the circular casing having openings in the lower sides, and a rotatable shaft journaled in said casing concentrically and provided with a sprocket-wheel, and a chain running on said sprocket-wheel, of the guard consisting of a metal plate bent into U shape and provided at its ends with laterally-bent flanges which engage the edges of the casing at the openings aforesaid, substantially as shown and described.

696,856. COMBINED STEAM AND INTERNAL-COMBUSTION MOTOR. FRED D. CLARK, McDonald, Pa. Filed May 30, 1901. Serial No. 91,068. (No model.)

Claim.—1. A combined steam and internal-combustion motor comprising a cylinder, a steam-chest, a spring-closed air and gas induction valve, a spring-closed check-valve for admitting the explosive mixture to one end of the cylinder and closing to prevent the escape of the same under compression, a valve in the steam-chest for controlling the supply of steam to the cylinder, steam, air and gas connections controlled by said valve, means for throwing the induction-valve and check-valve out of operation against the tension of their springs when the device is used as a steam-motor, means for throwing the valve in the steam-chest out of operation when the device is used as an explosive-motor, a gas-supply valve, and an adjustable system of levers connecting the said gas-supply valve with the air and gas induction valve, substantially as described.

2. In a combined steam and internal-combustion motor, the combination of a cylinder, a piston operating therein, a crank-shaft driven by

the piston, a steam-chest, an air and gas supply pipe, ports and passages communicating between the steam-chest, air and gas supply pipes and the opposite ends of the cylinder, a slide-valve in the steam-chest, an air and gas induction valve controlling the passage of air and gas into the steam-chest for admission to the cylinder, the check-valve for controlling the admission of explosive mixture to one end of the cylinder, means for holding the induction and check valves open for the free passage of the steam through the ports and passages controlled thereby, when the device is used as a steam-motor, means for throwing the slide-valve out of operation when the device is used as an internal-combustion motor, a valve in the gas-supply pipe, and variable connections between the air and gas induction valve and gas-supply valve for operating the latter, substantially as described.

3. In a combined steam and internal-combustion motor, the combination of a cylinder, a piston operating therein, a crank-shaft driven by the piston, a steam-chest, an air and gas supply pipe, ports and passages communicating between the steam-chest, air and gas supply pipes and the opposite ends of the cylinder, a slide-valve in the steam-chest, an air and gas induction valve controlling the passage of air and gas into the steam-chest for admission to the cylinder, the check-valve for controlling the admission of explosive mixture to one end of the cylinder, means for holding the induction and check valves open for the free passage of the steam through the ports and passages controlled thereby, when the device is used as a steam-motor, and means for confining the steam of the slide-valve for throwing said valve out of operation when the device is used as an internal-combustion motor, substantially as described.

4. In a combined steam and internal-combustion motor, and in combination with a cylinder, a steam-chest, air and gas supply pipes, and ports and passages communicating between the steam-chest, air and gas supply pipes and the opposite ends of the cylinder, an air and gas induction valve, a box or chamber therefor, having a threaded socket, a stem attached to the valve and sliding through said socket, a spring acting on the stem to hold the valve closed, and a threaded retreating-tube adapted to be inserted into said socket, to hold the valve open against the tension of said spring, substantially as described.

5. In a combined steam and internal-combustion motor, and in combination with a cylinder, a steam-chest, air and gas supply pipes, and ports and passages communicating between the steam-chest, air and gas supply pipes and the opposite ends of the cylinder, an air and gas induction valve, a gas-supply valve in the gas-supply pipe, a spring for closing the air and gas induction valve, means for holding said valve open against the tension of said spring, and a variable system of levers connecting the said induction-valve with the gas-supply valve, substantially as described.

6. In a combined steam and internal-combustion motor, and in combination with a cylinder, a steam-chest, air and gas supply pipes, and ports and passages communicating between the steam-chest, air and gas supply pipes and the opposite ends of the cylinder, an air and gas induction valve, a box or chamber therefor, a stem attached to the valve and sliding in the box, a spring acting on the stem to close the valve, and means for holding the valve open against the tension of said spring, a

gas-supply valve in the gas-supply pipe, and a system of pivoted operating-levers connecting the induction and gas supply valves, one of said levers being detachably connected with the stem of the induction-valve and another adjustably connected with the stem of the gas-supply valve, substantially as described.

7. In a combined explosion propelled and internal-combustion motor, a cylinder, a piston therein, a steam-chest, a slide-valve therein provided with dotted parallel flanges and a contact-piece, a valve-stem loosely mounted in the slot of the flanges and carrying a dog adapted to abut against the body of the valve and the contact-piece to move the valve toward and from its seat, and means for oscillating said stem, substantially as described.

696,857. COOKING STOVE OR RANGE. BEAVER CLARK, Seattle, Wash. Filed May 1, 1901. Serial No. 54,508. (No model.)

Claim.—1. A portable stove comprising vertical side walls disposed in triangular relation to each other, transverse partitions arranged horizontally therein to form ovens, and extending from side to side of the outer case, and separate vertical plates extending across the angles at the front side of the triangular casing from the front to the back walls, to close in the ovens and form smoke-flues alternately upon opposite sides of the series of ovens, substantially as described.

2. A portable stove comprising vertical side walls disposed in triangular relation to each other, transverse partitions arranged horizontally therein to form ovens, and extending from side to side of the outer case, and separate vertical plates extending across the angles at the front side of the triangular casing from the front to the back walls, to close in the ovens, and to form also smoke-flues and hot-air spaces, the said smoke-flues and hot-air spaces being alternately upon opposite sides of the ovens, substantially as described.

3. A heating apparatus comprising vertical side walls disposed in triangular relation to each other, transverse partitions forming ovens, smoke-flues formed in the angles at the front side of the triangular casing, alternately upon opposite sides of the ovens, closed hot-air spaces also formed in the angles at the front side of the triangular casing on a level with the ovens and on the opposite side of the same from the smoke-flues and a combined smoke-out pipe and ventilating-pipe for the ovens arranged in the back angle of the two rear sides of the casing substantially as and for the purpose described.

4. An apparatus of the nature indicated, comprising a body having a top and a fire-box beneath the top, a tier of cooking-compartments in the body intermediate said box and top and having doors, radiation-chambers interposed between the compartments and draft-openings to the chambers, a pipe passing through said tier, having its lower end closed and a vent for each compartment and a smoke-opening above the upper compartment beneath said top, a vertical flue in the wall of the first compartment from the fire-box to sides of contiguous compartments and a damper for each flue.

5. An apparatus of the nature indicated, comprising a casing composed of vertical back side walls disposed at right angles and a diagonal front side wall connected to the outer edges of the back walls, a top therefor and a fire-box at the base, a tier of cooking-compartments between said walls with door-openings through the front wall, radiation-chambers interposed between the compartments and draft-openings to the chambers, a pipe passing through said tier in the back corner having its lower end closed and a vent for each compartment and a smoke-opening above the upper compartment beneath said top, a vertical flue in one front corner

out of the first compartment leading from the fire-box to the first radiation-chamber and an air-chamber in the opposite corner of contiguous compartments and an air-chamber in the opposite corner and a damper for each fire.

696,858. BEDSTEAD. STEPHEN E. CLARK, Waltham, Wash. Filed June 10, 1901. Serial No. 68,573. (No model.)

Claim.—1. A bed having its post provided above and below its rail connection with sockets forming seats for the ends of a brace and having its rail provided with a keyhole-dial, the brace in the form of a bow formed at its ends to engage in the sockets of the post and provided at its middle with a threaded portion and passed through the keyhole-dial in the rail, with its threaded portion above and below the rail and the nuts on the brace above and below the rail substantially as set forth.

2. The improvement in beds comprising the post, the rail constructed for connection with the post the integral bow brace, and nuts adjustable on the brace above and below the rail, the ends of the brace being secured to the post on opposite sides of the rail, substantially as described.

3. The combination of the post and rail and means connecting the post and rail together, the detachable bow brace-rod extending through an opening in the rail and having the post at the ends of said brace, and means on said rod for securing it above and below said opening, substantially as described.

4. The post having a socket B' and a lateral recess or groove leading thereto, the rail, and the brace having a vertical axis in and held from longitudinal movement through the rail whereby it is held to the rail and may swing to adjust its end laterally into and out of the socket B'.

5. In a bedstead, the combination of the post, the rail, and a brace extending between the post and rail and adjustable in connection with said parts in the direction of its length substantially as set forth.

6. In a bedstead, the combination with the rail and the post to which said rail is connected of the brace-rod extended between the rail and post and having a vertical axis in connection with the rail and means for holding the brace from movement in the direction of such axis through the rail whereby the free end of the brace may be adjusted laterally into and out of engagement with the post substantially as set forth.

7. The combination of the post, the rail, the brace passed through the rail and engaged at its ends with the post, and nuts on the brace above and below the rail, substantially as set forth.

8. The combination of the post, the rail having a keyhole-dial, and the brace-rod extending between the rail and post and passed through the keyhole-dial in the rail and having means engaging with the rail adjacent to the keyhole-dial substantially as set forth.

9. In a bedstead, the combination of the post, the rail having an opening for the brace and the brace passed through the rail held between its ends to the said rail and engaged at its ends with the post on opposite sides of the rail, substantially as set forth.

696,859. ACETYLENE-GAS GENERATOR. JOHN E. CLARK, Hattop, Tex. Filed Oct. 31, 1901. Serial No. 68,591. (No model.)

Claim.—1. The combination is a gas-generator, of a water-tank, a bell, a hopper carried by and movable with the bell and having a lower opening forming a discharge-mouth, the walls of said opening being provided with a series of radial ribs forming yielding tongues, and an automatically-operated valve adapted to be closed on the closed portion of the hopper-mouth to close said mouth, the tongues being independently movable to permit of the closing of the valve in the event of the rotation of a portion of the carter between the edge of the valve and one or more of said tongues.

2. The combination is a gas-generator, of a water-tank, a gas-bell,

a hopper carried by and movable with the bell and having a removable cap or cover, there being in the lower portion of said hopper a discharge-opening, a valve-seat extending around the opening and formed of a series of independently-movable spring-tongues, a tube or casing depending from the mouth of the hopper to a point below the water-line of the tank, a valve-stem adapted for contact with the bottom of the tank, a conical valve carried by the valve-stem at a point within the mouth of the hopper, and a second conical valve also carried by said valve-stem at a point below the mouth of the hopper.

696,860. APPARATUS FOR JUDGING THE COLOR AND DENSITY OF PHOTOGRAPHIC NEGATIVES OR LIKE BOOKS. JOHN W. DAWSON, Bradford, England. Filed Dec. 10, 1900. Serial No. 39,347. (No model.)

Claim.—1. In an apparatus of the character described, and in combination, a movable disk having a series of graduated apertures therein, a casing having an aperture in the back corresponding to one of the apertures in the disk, and a further aperture in front, a semi-transparent screen behind the latter aperture, a tube having an aperture carrying a lens in line with the said two apertures, and independent apertures in said casing through which light may be transmitted through the light-permeable object and whereby it can be compared with the light transmitted through the other apertures and disk.

2. In apparatus of the character described and in combination, a disk having apertures graduated in size, a disk carrying tinted material of several shades, a casing having an aperture in the back in line with the apertures of said disk, means for carrying said disk so that they may be adjusted, and a further aperture in the casing through which the light may pass through the pervious object, and semi-transparent material covering said aperture in the casing.

696,861. GRAIN-CAR DOOR. DUNCAN BROWN and DANIEL W. DRAPEL, West Superior, Wis. Filed June 7, 1901. Serial No. 68,619. (No model.)

Claim.—1. A supplementary door for use inside the door-casing of a grain-car provided with an opening in its lower edge, a trap hinged at its upper edge in position to fill said opening when closed, upwardly-pointed hooks projecting inward from the lower edge of the trap, a rod pivoted on the inner side of the supplementary door provided with double crank bands adapted to engage said hooks for locking the trap, and means operable from the outside of the door for manipulating said rod, substantially as described.

2. A supplementary grain-car door, provided with an opening in its lower edge, a trap hinged at its upper edge in said opening and provided at its lower edge with notches, angularly-bent arms of sheet metal located in said notches and projecting in the form of upwardly-pointed hooks inside of the trap, screws for securing the inner flanges of the angular arms upon the outside of the trap, a rod pivoted upon the inside of the supplementary door and provided with crank bands adapted to engage said hooks, and a handle projecting through the supplementary door to the outside for manipulating said crank bands, substantially as described.

3. A supplementary door for grain-cars having an opening at its lower edge, a trap pivoted at its upper edge in said opening, upwardly-pointed, inwardly-projecting hooks at the lower edge of the trap, a rod pivoted on the inside of the supplementary door having crank bands adapted to engage with said hooks and bent at one end to form a handle, said handle projecting through a slot in the supplementary door and a locking-pawl pivoted to the outside of the supplementary door and adapted to hold the projecting handle in its locked position, substantially as described.

4. A supplementary door for use inside the door-casing of a grain-car provided with an opening in its edge, a trap hinged in position to fill said opening when closed, a hook carried by the inner face of said trap, a rod pivoted on the inner side of the supplementary door provided with a crank band adapted to engage said hook for locking the trap, and means for rotating said rod for bringing said crank band into and out of engagement with said hook, substantially as described.

5. A supplementary grain-car door, provided with an opening, a trap hinged to said door in position to fill said opening, hooks projecting inwardly from the inner face of said trap, a rod pivoted to said door and extending longitudinally across said trap, crank bands formed in said rod and adapted by rotation of said rod to be brought into engagement with said hooks for locking said trap in a closed condition, means outside said door for rotating said rod, and means for preventing such rotation, substantially as described.

6. A supplementary grain-car door, provided with an opening, a trap hinged to said door in position to fill said opening, hooks projecting inwardly from the inner face of said trap, a rod pivoted to said door and extending longitudinally across said trap, crank bands formed in said rod and adapted by rotation of said rod to be brought into engagement with said hooks for locking said trap in a closed condition, means outside said door for rotating said rod, and means for preventing such rotation, substantially as described.

7. A supplementary grain-car door, provided with an opening, a trap hinged to said door in position to fill said opening, hooks projecting inwardly from the inner face of said trap, a rod pivoted to said door and extending longitudinally across said trap, crank bands formed in said rod and adapted by rotation of said rod to be brought into engagement with said hooks for locking said trap in a closed condition, means outside said door for rotating said rod, comprising a portion of said rod bent at an angle and extending through a slot in said door thereby forming a handle, and a pawl pivoted to said door and adapted to swing into the path of movement of said handle and engage the same for locking it against movement, substantially as described.

696,862. GAME. LOUIS BROWN, Reading, Ohio. Filed June 29, 1901. Serial No. 68,592. (No model.)

Claim.—1. A game-board comprising a parallel series of tunnels each having a ball-opening extending through different parts of the surface of the board, a pan into which the balls are discharged, a receptacle for facilitating the manipulation of the board and a depending strip adapted to provide a stop at the rear side of the board.

2. The herein-described game apparatus comprising a game-board, an upwardly-convex rim therefor, and parallel strips or guards forming an elongated terminal pan at one side of the board, the board being provided in its upper surface with openings communicating with narrowways leading from each opening to the terminal pan, an initial ball-rest located opposite the terminal pan, rolling elements adapted to traverse the surface of the board and to enter said openings and pass through the narrow-

ways into the terminal pan, a fulcrum post or rocker extending downward from the bottom of the board, and a stop extending downward from one side of the board for the purpose of limiting the rocking movement of such board.

696,868. ROLLER BALING-PRESS. JAMES J. FAHLEH, Minneapolis, Tenn. Filed May 20, 1901. Serial No. 68,631. (No model.)

Claim.—1. In a roller baling-press, the combination with a stationary roll, a pivoted frame and rolls mounted in said frame above the stationary roll and parallel therewith, of a hydraulic cylinder exerting a downward pressure on the pivoted frame, a by-pass connecting the ends of the cylinder, a valve in said by-pass, a spring pressing against said valve and means connecting said spring with the pivoted frame.

2. In a roller baling-press, the combination with a stationary roll, a pivoted frame, and rolls mounted in said frame above the stationary roll and parallel therewith, of a cylinder containing liquid, mounted beneath the frame, a piston in said cylinder connected to the frame, a spring-pressed valve regulating the escape of liquid at the upper end of said cylinder, and means connected with the frame for increasing the tension on said spring-pressed valve as the frame is raised by the rolls.

3. In a roller baling-press, the combination with a stationary roll, a pivoted frame, rolls mounted in the frame parallel with the stationary roll, a turn-back platform pivoted at one end beneath the rolls and rigidly connected at its free end to the free end of the pivoted frame, and means for retarding the upward movement of the platform.

4. In a roller baling-press, the combination with a stationary roll, a pivoted frame and rolls mounted in the free end of the frame parallel with the stationary roll, of a pivoted platform comprising two curved or turbo-back plates riveted together at their side edges forming a hollow shell, here or rods connecting the free ends of the platform and pivoted frame to prevent twisting of the rolls out of parallel, and means for retarding the upward movement of the platform and pivoted frame.

5. In a roller baling-press, the combination with a lower stationary roll, a pivoted frame, upper rolls mounted in the frame parallel with the lower roll, of a drive-shaft, a chain or gearing connecting the drive-shaft and lower roll, a gear loose on the drive-shaft, a clutch for locking said gear and shaft together, transmitting mechanism operated by said gear to revolve the upper rolls, a crank-shaft for operating the clutch, and a rod connected to the pivoted frame for operating the clutch as the bale is formed or doffed.

6. In a roller baling-press, the combination with a lower stationary roll, a pivoted frame, upper rolls mounted in said frame parallel with the lower roll and mechanism for transmitting motion to revolve all of said rolls in the same direction, of a cylinder to contain liquid, a piston in said cylinder, a rod connecting said piston and pivoted frame, said cylinder hinged at its lower end to permit the piston a direct pull against the frame in all its varying positions, a regulating-cylinder beside the main cylinder and communicating therewith at both ends, a valve opening in the upper end of said regulating-cylinder in the path of flow of the liquid, a rod projecting through said regulating-cylinder and connected to the pivoted frame, a coiled spring carried by the rod and pressing against the valve and adapted to increase the pressure thereagainst as it is contracted by the upward rise of the pivoted frame due to the increase in size of the bale.

7. A roller for a baling-press, comprising beads or spindles, and a cylinder made of abrasive material and supported by said beads or spindles, the exterior face of said abrasive cylinder being grooved spirally.

8. In a roller baling-press, the combination of a frame, presser-rolls mounted in said frame and a swinging frame mounted on the first-mentioned frame in front of the rolls to hold and guide the baling-cloth.

696,864. SELF-EXTINGUISHING NON-EXPLOSIVE LAMP.
THOMAS E. FREEMAN and THOMAS M. HENDERSON, Portsmouth, Va.
Filed Sept. 4, 1901. Serial No. 74,315. (No model.)

Claim.—1. A self-extinguishing non-explosive lamp, comprising a relief-valve in communication with the fuel, a cut-off adapted to be moved across the wick-tube, and suitable connection between the valve and cut-off whereby the valve actuates the cut-off.

2. A self-extinguishing non-explosive lamp, comprising a valve in communication with the fuel, a cut-off adapted to operate across the wick-tube, a cut-off lever connected therewith, and a link interposed between said lever and the valve and actuated by the valve.

3. A self-extinguishing non-explosive lamp, comprising a valve in communication with the fuel, a cut-off adapted to move across the wick-tube, an operative connection between the cut-off and valve, a spring for holding the valve to its seat, and means for adjusting the tension of said spring.

4. A self-extinguishing non-explosive lamp, comprising a valve in communication with the fuel, a cut-off operating across the wick-tube, an operative connection between the valve and cut-off, a valve-closing spring having one end fixedly connected to the valve, and a key engaging the coils of the spring, the arrangement being such that by rotating the valve the coils of the spring may be successively engaged with the key for the purpose of increasing or diminishing the tension of the spring.

5. A self-extinguishing non-explosive lamp, comprising a spring-actuated relief-valve in communication with the fuel, a cut-off operating across the wick-tube, a link pivotally connected at one end to the cut-off lever and at its opposite end to the valve, and a hand-operated chain one of the links of which forms the pivotal connection between the valve and link.

696,865. DIE FOR COVERING TUBES. PATRICK H. FRIE,
Kansas, Wis. Filed Jan. 11, 1901. Serial No. 56,592. (No model.)

Claim.—1. The die for covering round metal surfaces with an external jacket, consisting of a block having a hole through the same opening on the upper surface of said block, a higher block having an opening through it with a V-shaped notch in its side and a filler attachment to the upper surface of the first-mentioned block on one side of its opening and having two extensions, one extending outwardly, and the other one extending inwardly into the V-shaped notch of the opening of the higher block substantially as described.

2. The die for covering round metal surfaces with an external jacket, consisting of a block having a hole through the same opening on the upper surface of said block, another block having an opening through it with a V-shaped opening in its side, a filler attached to the upper surface of the first-mentioned block on one side of its opening and having two extensions one extending outwardly and the other one extending inwardly into the V-shaped notch of the opening of the higher block, and a third block having a plain round hole disposed behind the other blocks and adapted to fit over the curved edge of the jacket substantially as and for the purpose described.

696,866. TRACK-JACK. OLAF FAYE, Rugby, and LOUIS E. JENSEN, Rindberg, N. D. Filed Aug. 2, 1901. Serial No. 70,009. (No model.)

Claim.—1. A track-jack comprising a stand, a toothed lifting-bar slidably mounted thereon, a horizontal shaft having its ends grooved and mounted in the frame of the stand, retaining-arms passing through openings in the stand and entering said grooves, a toothed wheel mounted on said shaft and cooperating with the lifting-bar, an operating-lever pivoted to the frame of the stand, formed with a recess and slot, a spring located in the recess, and a dog located in the slot, having studs working in the slot, and cooperating with the teeth of said wheel.

2. A track-jack comprising a stand, a toothed and sliding lifting-bar, an operating-lever pivoted to a horizontal shaft connected with the frame of the stand, a toothed wheel mounted on the same shaft, and engaging the lifting-bar, a dog on the lever engaging said toothed wheel, and a spring-controlled retaining-dog pivotally mounted on the stand and comprising a pair of engaging lips or points, one of which cooperates with the lifting-bar and the other of which is adapted to be engaged by the operating-lever for tripping the dog.

696,867. COMPOUND STEAM-TURBINE. JOHN F. PULLAR,
Bristol, Newcastle-upon-Tyne, England. Filed Apr. 13, 1901. Serial No. 54,628. (No model.)

Claim.—1. In a turbine, the combination with the spindle and its casing, of rings of blades fixed to the said spindle, and intermediate rings of blades fixed to the casing, the free ends of each of said rings of blades being connected together and arranged to leave a wide space between them on the spindle and the interior of the casing and between these in the casing and the exterior of the spindle and to form nearly fluid-tight lateral joints with annular surfaces carried by the casing and spindle respectively and thereby cause practically the whole of the motive fluid used to pass through the rings of blades.

2. In a turbine, the combination with the spindle and its casing and rings of blades fixed to said spindle and casing, of annular buffers fixed to the free ends of the blades, and transversely-arranged annular faces located in the annular space between said spindle and casing and adjacent to which the edges of said buffers terminate.

3. In a turbine, the combination with the spindle and its casing and rings of blades fixed to said spindle and casing, of annular buffers fixed to the free ends of the blades, and transversely-arranged annular projections extending outwardly from the spindle and inwardly from the casing and adjacent to the flat faces of which the edges of said buffers terminate.

4. In a turbine, the combination with the spindle and its casing, of rings of blades fixed at one end to holding-rings fixed to the exterior of the spindle and the interior of the casing and having flat annular lateral faces, and buffers fixed to the free ends of the rings of blades and arranged adjacent to said annular faces.

5. In a turbine, the combination with the spindle and its casing and rings of blades fixed to said spindle and casing, of annular buffers fixed to the free ends of the blades as to leave considerable radial clearance between the buffers fixed to the inner ends of the fixed blades and the spindle, and between the buffers fixed to the outer ends of the rotary blades and the interior of the casing, and annular faces carried by the spindle and casing and arranged in close proximity to but out of contact with the buffers on the fixed and rotary blades respectively, substantially as described for the purpose specified.

6. In a turbine, the combination with a ring of blades fixed at one end to a carrier, of a laminated annular buffer fixed to the other end of the ring of blades and having successive buffing edges spaced apart so as to form one or more annular spaces between them, and a transversely-arranged annular face arranged near to but not in contact with said edges of the buffer.

7. In a turbine, the combination with a ring of blades fixed at one end to a carrier, of a laminated annular buffer fixed to the other end of the ring of blades and having successive buffing edges spaced apart so as to form one or more annular spaces between them, and a transversely-arranged annular face arranged near to but not in contact with said edges of the buffer.

8. In a turbine, the combination with a ring of blades fixed at one end to a carrier, of a laminated annular buffer fixed to the other end of the ring of blades and having oppositely-arranged buffing edges at its respective sides, and transversely and oppositely arranged annular faces located near to but not in contact with the opposite edges of said buffer.

9. In a turbine, the combination with a ring of blades fixed at one end to a carrier, of a laminated annular buffer fixed to the other end of the ring of blades and having successive buffing edges at each side, and transversely and oppositely arranged annular faces located near to but not in contact with the opposite edges of the said buffer.

10. In a turbine, the combination with the spindle and casing and rings of blades fixed alternately to said spindle and casing, of laminated annular buffers fixed to the free ends of said rings of blades, and each having two or more superposed buffing edges, and two sets of rings carried by said spindle and casing respectively and having laterally-arranged annular faces arranged near to but not in contact with the superposed edges of said buffers.

11. In a turbine, the combination with the spindle and casing and

rings of blades fixed alternately to said spindle and casing, of laminated annular buffers fixed to the free ends of said rings of blades and each having two or more superposed buffing edges spaced apart so as to form intervening annular spaces, and two sets of rings carried by said spindle and casing respectively and having laterally-arranged annular faces arranged near to but not in contact with the superposed edges of said buffers.

12. In a turbine, the combination with the spindle and casing, of rings of blades fixed to said spindle, intermediate rings of blades fixed to said casing, annular buffers fixed to the free ends of each of said rings of blades and arranged to leave a deep radial space between them and the adjacent part of the casing and spindle respectively, laterally-arranged annular surfaces carried by said spindle and casing and arranged in close proximity to the edges of the buffers on the fixed and rotary rings of blades respectively, and means for adjusting said spindle with its rings of blades, buffers and annular surfaces, and vice versa in relation to the casing and its rings of blades, buffers and annular surfaces and for holding said spindle and vice versa.

13. In a turbine, the combination with the spindle and casing, of rings of blades fixed to each of these parts, the free end of each blade being formed with a projection, an annular buffer secured to the projections of each ring of blades as to close the space between the outer ends of said ring of blades and having one or more buffing edges, and transverse annular surfaces carried by said spindle and casing and located near to but not in contact with the edges of said buffers.

14. In a turbine, the combination of a stepped spindle and casing arranged one within the other with an annular space between the two, and rings of blades fixed to said spindle and casing and extending into said annular space, of balancing means arranged to act upon the enlarged end of said spindle and force it outward in an opposite direction to that of the steam flowing through said annular space.

15. In a turbine, the combination of a stepped spindle and casing arranged one within the other so as to leave an intermediate space between the annular end face of the enlarged end of said spindle and the adjacent end wall of said casing, and means for admitting motive fluid to said space for the purpose set forth.

16. In a turbine, the combination of a stepped spindle and casing arranged one within the other so as to leave an annular space between the stepped portions thereof and between the annular end face of the enlarged portion of said spindle and the adjacent end wall of said casing, said space being in communication one with another, and rings of blades fixed to said spindle and casing and extending into said annular space.

17. In a turbine, the combination of a stepped and bladed spindle and casing arranged one within the other so as to leave a longitudinal annular space between the stepped portions thereof and also an annular end space between the annular end face of the enlarged portion of said spindle and adjacent end wall of said casing, said casing having an inlet-passage at its smaller end and an exhaust-passage at its larger end, said spindle being formed with symmetrically-arranged longitudinal passages connecting said annular spaces, and said annular end space being in communication with said exhaust-passage, and buffing means arranged in said end space between said longitudinal passages and said exhaust-passage.

18. In a turbine, the combination of a stepped and bladed casing having an inlet-passage at its smaller end and an exhaust-passage at its larger end, a stepped and bladed spindle arranged within said casing so as to form a longitudinal annular space between the stepped portions of the two and an annular end space that is located between the annular end face of the enlarged portion of the spindle and the adjacent end wall of the casing and is in communication at its outer periphery with said exhaust-passage, symmetrically-arranged longitudinal passages formed in said spindle and connecting said longitudinal and end spaces, and a buffing arrangement comprising concentrically-arranged rings located in said end space between said longitudinal passages and said exhaust-passage and carried by one of the walls of said space and terminating near to but not in contact with the opposite end wall of said space.

19. In a turbine, the combination of a stepped and bladed casing having an inlet-passage at its smaller end and an exhaust-passage at its larger end, a stepped and bladed spindle arranged within said casing so as to form a longitudinal annular space between the stepped portions of the two and an annular end space that is located between the annular end face of the enlarged portion of the spindle and the adjacent end wall of the casing and is in communication at its outer periphery with said exhaust-passage, symmetrically-arranged longitudinal passages formed in said spindle and connecting said longitudinal and end spaces, and a buffing arrangement comprising two sets of concentrically-arranged rings located in said end space, one set being carried by the annular end face of the enlarged portion of said spindle and the other set being carried by the opposite end wall of said casing and alternating in position with the rings in the first-mentioned set, said buffing arrangement being arranged between said longitudinal passages and said exhaust-passage.

20. In a turbine, the combination of a stepped and bladed spindle

and casing arranged one within the other so as to form a longitudinally-arranged annular working space between the stepped portions thereof, and an annular balancing-space between the larger end of said spindle and the adjacent end of said casing, said balancing-space being in communication at one end with the longitudinal annular space and at the other end with the exhaust-passage leading from said casing, and a holding device located in said balancing-space and comprising concentrically-arranged laminated rings each fixed at one end to one of the end walls of said balancing-space and having its opposite edge splined apart and terminating in proximity to the opposite end wall of said space.

21. In a turbine, a stepped and bladed spindle and casing arranged one within the other so as to leave between the larger end of the stepped portion of said spindle and the adjacent end wall of said casing an annular space one of the end walls of which is formed with concentric annular grooves, and holding-rings fixed in some or all of the grooves in each wall.

22. In a turbine, a stepped and bladed spindle and casing arranged one within the other so as to leave between the larger end of the stepped portion of said spindle and the adjacent end wall of said casing, an annular space each of the end walls of which is formed with concentric annular grooves, and holding-rings fixed in some or all of the grooves in each wall.

23. In a turbine, a stepped spindle comprising a central shaft and a number of sleeves, the inner sleeve being placed on said shaft and the others one over another, each sleeve being successively larger in diameter but shorter than the one it immediately surrounds and the whole of them being attached one to another and to said shaft.

24. In a turbine, a casing having a stepped and bladed interior, a stepped and bladed spindle arranged within said casing so as to form between its stepped portion and the corresponding part of the casing, a longitudinal annular space, and between its larger end and the adjacent end of said casing, an annular space that is in communication with the exhaust-passage from said casing, and a holding arrangement in said space, the stepped portion of said spindle being built up of a number of superposed sleeves each of which, except the outermost one, is formed with concentrically-arranged longitudinal grooves or channels connecting the annular space between the stepped portions of said casing and spindle with the annular space.

25. In a turbine, a ring of blades comprising a number of radially-arranged blades and a compound holding-ring in which the roots of said blades are secured.

26. In a turbine, a ring of blades comprising a number of radially-arranged blades and a compound holding-ring comprising two bent strips of metal arranged side by side and having their adjacent edges formed with notches in which the roots of said blades are fixed.

27. In a turbine, a ring of blades comprising a number of radially-arranged blades each having its root and split and the separate portions thereof bent apart, and a compound holding-ring made of two bent strips of metal having their adjacent edges notched to receive and hold the split ends of the blades.

696,868. CIGAR-PACKING MACHINE. JOHN G. GABLE, Boston, Mass. Filed June 5, 1901. Serial No. 63,596. (No model.)

Claim.—1. In a cigar-packing machine, an open box, a follower-slide arranged within the box, an adjustable head-block mounted within one end of the box, a setting-curve carried by the head-block and cooperating with said slide, and a pressure-rod also carried by the head-block and cooperating with said slide.

2. In a cigar-packing machine, the box-body having a fixed end plate and provided with a slide-opening, a follower-slide working through said opening and having a head and a retaining-arm, an adjustable head-block mounted within the open end of the box, said head-block having a guide-opening for said retaining-arm, separate retaining devices adjustably connecting the head-block with the back and bottom of the box, and a setting-curve and a pressure device both supported by said head-block.

3. In a cigar-packing machine, an open box, a follower-slide arranged within the box, a head-block arranged within one end of the box, a setting-curve loosely extending through the head-block and pivoted to the follower-slide, a lever act arranged on the upper, and a pivotal pressure-rod supported by the head-block.

696,869. MOTOR-DRIVE. HARMONY F. CHAMBERLAIN, Rochester, N. Y., assignor to John E. Chamberlain, Rochester, N. Y. Filed May 12, 1901. Serial No. 63,600. (No model.)

Claim.—1. In a motor-drive, the combination of a disk, and flexible picture-cards mounted perpendicularly in an endless series on the face of the disk.

2. In a motor-drive, the combination of a disk, and picture-cards mounted in a plane perpendicular to said disk, said picture-cards being arranged radially on the surface of said disk.

3. In a motor-drive, the combination of a disk, flexible picture-cards mounted in a plane perpendicular to said disk, and means for supporting and rotating said disk.

4. In a motor-drive, the combination of a disk, an endless series of picture-cards mounted on the face thereof, a thumb engaging said picture-cards at a certain period of the revolution of said disk, and means for rotating said disk.

5. In a motor-drive, the combination of an indexing casing provided with an observing-aperture, a thumb secured to said casing, a horizontal disk provided with annular washers, picture-cards vertically mounted on said disk between said annular washers, and means for supporting said disk, and means for rotating said disk.

6. In a motor-drive, the combination of an indexing casing provided with an observing-tube, a thumb secured to said casing, a table or support provided with an upwardly-projecting annular washer, a disk provided with a downwardly-projecting annular washer, and picture-cards between said annular washers, said disk being also provided with concentric annular washers on its upper surface, and picture-cards secured to said disk between said annular washers perpendicular to said surface and radially arranged thereon, and means for rotating said disk.

7. In a motor-drive, the combination of a disk, flexible picture-cards mounted perpendicularly in an endless series on the face of the disk, and a thumb for detaching and snapping said cards into view when moved relatively thereon.

696,870. MACHINE FOR CLEANING AND SORTING RAISINS. EDWARD J. KAMMEL, Toledo, Ohio, assignor to the Dew and Shell Company, Toledo, Ohio. Filed May 26, 1901. Serial No. 61,100. (No model.)

Claim.—1. A machine for cleaning and sorting raisins, comprising a receiver, a vertically-arranged tube leading therefrom, a tube leading from the opposite side of said receiver, an exhaust-fan at the end of said last-mentioned tube, a controller-valve interposed between said fan and receiver, whereby a draft may be controlled, means for supplying raisins to said tube, a receptacle for receiving raisins from the lower end of said tube, having a discharge-opening at its bottom for removing the products deposited therein and providing openings to permit of the passage of air into the lower end of the vertical tube, substantially as described.

2. A machine for cleaning and sorting raisins, comprising a vertical section-tube open at its lower end, a supply-receiver at the upper end of said tube, a fan for creating a draft within said tube and receiver, means for supplying raisins to said tube near its lower end, a return-band at the upper end of the section-tube for deflecting to the receiver the products carried upward by said draft, an auxiliary receiver carried by the lower end of said supply-receiver, a valve for discharging the products from the supply-receiver into the auxiliary receiver, and a valve for discharging said products from the auxiliary receiver, whereby the supply-receiver may be emptied while the machine is in operation, substantially as described.

3. A machine for cleaning and sorting raisins, comprising in its construction a main receiver, a tube projecting from the receiver, an exhaust-fan at the outer end of the tube, a valve interposed between the fan and receiver, means for manually operating said valve, a vertical section-tube discharging at its upper end into said main receiver, means for supplying raisins to said section-tube, a plate within the main receiver for deflecting the air-draft, an auxiliary receiver beneath deflecting-plate of the main receiver and communicating with the main receiver, a valve for controlling such communication, a valve for emptying the auxiliary receiver, and means for controlling said emptying-valve, whereby said receiver may be emptied while the machine is in operation, substantially as described.

696,871. TAKE-UP MECHANISM FOR SEWING-MACHINES. JAMES L. KIEFFER, Montreal, Canada. Original application filed Aug. 24, 1901, Serial No. 73,501. Divided and this application filed Nov. 14, 1901. Serial No. 63,597. (No model.)

Claim.—1. In a sewing-machine of the class described, a thread-take-up mechanism comprising a revoluble member having a face adapted for engagement by the thread, a lever, a thread-pulling fork carried by the lever and arranged to be moved thereby across the path of the thread having said revoluble member on its way to the stitch mechanism, and means caused to be operated by the motion of said lever to lock the revoluble member against rotation during such traversing movement of the thread-pulling fork, substantially as described.

2. In a sewing-machine of the class described, a thread-take-up mechanism comprising a compound-ratchet mechanism having means for preventing rotation thereof in one direction and also provided with a thread-engaging face, an automatic pawl adapted to lock said ratchet against rotation in an opposite direction, a ratchet engaging with said automatic pawl, a lever riding upon the ratchet, and means for taking up the slack thread at the same time that the ratchet is locked by the automatic pawl, substantially as described.

3. In a sewing-machine of the class described, a thread-take-up mechanism comprising a compound ratchet, a check-pawl engaging with one ratchet member, an automatic pawl adapted to engage with the other ratchet member, a ratchet having an effect on the back-carriage thereof and operatively connected with the automatic pawl, a lever arranged to ride on the back-carriage of the ratchet and adapted to normally rest on the effect thereof, and means for pulling up the slack thread from the needle on the taking engagement of the automatic pawl with said ratchet, substantially as described.

4. In a sewing-machine of the class described, a thread-take-up mechanism comprising a compound ratchet, a check-pawl, an automatic pawl, a ratchet connected with the automatic pawl, a cam-actuated lever provided with a footpiece and with a shoe which rides on the ratchet, and a thread-pulling fork extending from the footpiece and movable with the lever, substantially as described.

696,872. TENSION MECHANISM FOR SEWING-MACHINES. JAMES L. KIEFFER, Montreal, Canada. Original application filed Aug. 24, 1901, Serial No. 73,501. Divided and this application filed Nov. 14, 1901. Serial No. 63,598. (No model.)

Claim.—1. In a tension mechanism for sewing-machines, the combination with a tension-wheel, means for normally retarding the rotation thereof, and a lever which controls the retarding means, of a tappet-rod carried by a rotary part of the sewing-machine, a releasing-lever having operative connection with said controlling-lever, and a tappet-arm yieldably supported by the releasing-lever in a position to be engaged by the tappet-rod to actuate said lever when said tappet-rod is turning in a backward direction but to ride over said tappet-rod without being engaged by the same in the normal forward operation of the machine.

2. In a tension mechanism for sewing-machines, the combination with a tension-wheel, a spring-pressed friction-disk and a controlling-lever engaging with said disk, of a tappet-rod carried by a rotary part of the sewing-machine, a releasing-lever having operative connection with the controlling-lever, and a tappet-arm yieldably mounted on the releasing-lever and disposed in a position for engagement by the tappet-rod, as set forth.

3. In a tension mechanism for sewing-machines, the combination with a tension-wheel, a spring-pressed friction-disk and a controlling-lever engaging with said friction-disk, of a releasing-lever having operative connection with said controlling-lever, means for limiting the movement of the releasing-lever, a spring to normally hold the releasing-lever in one position, and a tappet-arm yieldably supported on the releasing-lever and disposed in the path of the tappet-rod, as set forth.

4. In a tension mechanism for sewing-machines, the combination with a tension-wheel, a spring-pressed friction-disk for restraining its motion, and a controlling-lever engaging with said friction-disk, of a releasing-lever having operative connection with said controlling-lever, means for yieldably retaining said releasing-lever in one position, a shaft having a hand-wheel thereon, a disk carried by said wheel and having a stud projecting laterally therefrom, and a pawl or detent yieldably supported upon the end of the releasing-lever and disposed in the path of said stud in such manner as to be engaged by said stud to throw back the releasing-lever and the controlling-lever to release the tension mechanism when said hand-wheel is given a partial backward rotation but to permit said stud to pass over said detent without operating said lever in the normal forward operation of the machine.

5. In a tension mechanism for sewing-machines, the combination of a shaft having a hand-wheel thereon, a stud projecting laterally from said shaft at one end and concentrically thereof, a releasing-lever having a yieldably-supported pawl or tappet-arm extending into the path of said

rod and having an abrupt flange, whereby the normal forward operation of said shaft causes the said flange to depress said pawl without operating the lever but a partial backward rotation of the same causes the said flange to engage said abrupt shoulder to turn the lever about its axis, a tension-wheel, returning means engaging the same to put tension on the thread, and a two-armed lever connected at one end to said releasing-lever and at the opposite end to said returning means, whereby the operation of said lever in the manner aforesaid causes said returning means to be drawn back to release said tension-wheel, substantially as described.

696,873. GRAB-HOOK. DAVID H. LAMAR, Union, Pa. Filed Jan. 8, 1902. Serial No. 51,915. (No model.)

Claim.—1. A grab-hook comprising a shank and hooked portion the rear face of said shank being provided with a thickened or widened flange terminating at the rear of the tooth portion in a shoulder, there being a recess formed between the shoulder and the rear of the hook.

2. A grab-hook comprising a main shank and a hooked portion, there being a recess formed at the rear of the tooth and extending beyond the plane of the inner face of the shank.

3. A grab-hook having a shank 1 provided with a terminal eye 2, a hook 3, a shoulder 4 disposed to the rear of the hook and forming a continuation of the thickened flange at the outer rear wall thereof, there being an engaging recess for an extending-rod formed between the shoulder and the rear face of the tooth, substantially as specified.

696,874. SHIMS-FORMING MACHINE. WILLIAM E. LAVIS, Gloucester, Mass. Filed Sept. 20, 1900. Serial No. 31,448. (No model.)

Claim.—1. A machine for heating the para-line of coils, comprising a suitable frame, a power-shaft mounted therein, para-line-engaging drums or wheels loosely mounted on said shaft, a gearing connecting the shaft with the said wheels for driving said wheels, whereby the wheels may be turned at a greater or less speed in the same direction by reversing the said shaft, substantially as described.

2. In a machine for heating the para-line of coils, the combination with a suitable standard, of a shaft therein, grooved pulleys or drums mounted loosely on the said shaft, gearing connecting the shaft with the pulleys, and means for controlling the said gearing whereby the drums will be moved at the same speed as their shaft or at a less speed with greater power, substantially as described.

3. A machine for heating the para-line of coils, comprising a standard, a shaft mounted therein, grooved wheels loosely mounted upon said shaft, gearing interposed between the shaft and the wheels for driving the wheels at different speeds according to the direction in which the shaft is turned, and means for controlling the said gearing, whereby one of the wheels may be thrown out of engagement with the said shaft, while the other continues its operation, substantially as described.

4. A machine for heating the para-line of coils, comprising a standard, a shaft mounted therein, grooved pulleys loosely mounted on the said shaft, double ratchet-wheels mounted on the said shaft, gearing carried by the said ratchet-wheels and connecting the shaft with the said grooved wheels, and pawls for controlling the movement of said double ratchet-wheels, the structure being such that the power and speed of the grooved wheels may be changed by merely reversing the shaft, substantially as described.

5. A machine for heating the para-line of coils, comprising a standard, a shaft mounted therein, grooved pulleys loosely mounted thereon and having internal gear arranged upon their peripheries, double ratchet-wheels loosely mounted on the said shaft, actuating-pieces mounted between the ratchet-disks of the said double ratchet-wheels, the said gearing communicating motion from the shaft to the grooved wheels, pawls mounted upon the standard for holding the double ratchet-wheels against motion in one direction, and pawls carried by the grooved wheels for preventing the said double ratchet-wheels from moving in one direction with respect to said grooved wheels, the structure being such that when the shaft is turned in one direction the gearing will impart a comparatively slow movement to the grooved wheels with considerable power, and when the shaft is turned in the opposite direction the gearing will communicate motion to the grooved wheels at a greater speed but with less power.

6. A machine for heating the para-line of coils, comprising a standard, a power-shaft mounted therein, para-line-engaging wheels mounted on the said shaft, double ratchet-wheels also mounted on said shaft and comprising ratchet-disks having teeth upon their peripheries arranged in opposite directions with respect to each other, means for spacing the said disks a proper distance from each other, a pinion mounted between the disks of each double wheel and keyed to the shaft so as to turn therewith, gear-wheels pivoted between the disks of the said double wheels and meshing with the pinion secured to the shaft, the said gear-wheels also meshing with racks upon the inner surface of the para-line-engaging wheels, and pawls adapted to engage the teeth upon the peripheries of the double ratchet-wheels, whereby the speed of the drums or para-line-engaging wheels may be controlled by reversing the shaft, substantially as described.

7. A machine for heating the para-line of coils, comprising para-line-engaging wheels, a shaft for loosely supporting the same, a standard supporting the shaft, double ratchet-wheels loosely mounted on the said shaft and comprising disks spaced from each other and provided with ratchet-teeth upon their peripheries extending in opposite directions, gearing between the said disks and connecting the shaft with the para-line-engaging wheels, pawls upon the standard for engaging the inner disks of the double ratchet-wheels of the outer ratchet-wheel disks, and means for holding either set of pawls out of engagement with their respective disks, upon one side of the machine or the other, whereby one para-line-engaging wheel may be stopped while the other continues its motion, so that one side of the coils may be heated at a time, substantially as described.

8. A para-line heating machine comprising a standard, a shaft mounted therein, para-line-engaging wheels mounted on said shaft, double ratchet-wheels also mounted on the said shaft, gearing connecting the shaft with the para-line wheels, gravity-pawls carried by the said wheels and engaging one set of teeth upon the double ratchet-wheels, a cord or wire connecting the two ends of said pawls, whereby the said pawls may be held out of engagement with the ratchet upon placing the said cord or wire over a pin or projection on the said para-line wheel, pawls pivoted to the said standard and adapted to engage the inner teeth upon the ratchet-wheels and a pivoted T-shaped piece adapted to engage the outer ends of said pawls, whereby one or the other thereof may be held out of engagement with the ratchet-wheels, the structure being such that the para-line wheel on either side of the machine may be thrown out of engagement with the other is operating, and the wheel which is operating may be changed in speed when desired and a third set of pawls mounted upon the standard and engaging the periphery of the para-line wheels, teeth formed upon the periphery of said wheels adapted to be engaged by the said pawls, whereby the wheels will be prevented from turning except in one direction, and means for holding the para-line in engagement with the grooved wheels, substantially as described.

9. In a machine for heating the para-line of coils, the combination with a wheel adapted to engage a para-line, of a shaft for turning said wheel, gearing interposed between the shaft and the wheel, means for locking the gearing so that the wheel will be turned with the shaft at the same speed in which the shaft turns, and means causing the gearing to operate when unlocked and the shaft is reversed so that the wheel is turned with more power but at a less speed than before but in the same direction, substantially as described.

10. In a machine for heating the para-line of coils, the combination with wheels or drums for engaging the said para-line, of reversible gearing for turning the said wheels at different speeds according to its re-

versal, and means for throwing either of the said wheels out of engagement with the said gearing without interfering with the operation of the other wheel, whereby one line may be passed while the other is stopped and vice versa, without stopping the operation of the machine, substantially as described.

11. A machine for heating a para-line of a mine, comprising a suitable frame, a power-shaft mounted therein, a para-line-engaging drum or wheel loosely mounted on said shaft, a gearing connecting the shaft with the said wheel for driving the said wheel, whereby the wheel may be turned at a greater or less speed in the same direction by reversing the said shaft, substantially as described.

12. In a machine for heating a para-line of a mine, the combination of a suitable standard, of a shaft therein, a grooved pulley or drum mounted loosely on the said shaft, gearing connecting the shaft with the pulley, and means for controlling the said gearing, whereby the drum will be moved at the same speed as its shaft or at a less speed with greater power, substantially as described.

696,875. BICYCLE-TIRE. ROBERT L. LOWE, San Francisco, Cal. Filed Oct. 14, 1898. Serial No. 72,204. (No model.)

Claim.—1. In a bicycle-tire, the combination with the rim of a wheel, of a plurality of springs secured thereto and arranged in the form of segments upon said rim adapted to engage the rim, and a resilient tread engaging the springs and provided on its under side with a depending portion which projects between the free ends of the springs.

2. In a bicycle-tire, the combination with the rim of a wheel, of circular rings arranged beneath the tread thereof, a plurality of springs spaced apart and having open ends on their lower portions and having their upper portions secured to the said rings, and strips of fibrous material arranged on the free ends of the springs, and secured to the springs by the said rings.

3. In a bicycle-tire, the combination with a plurality of springs adapted to be secured to the rim of the wheel and provided with a segmental curved portion and upwardly and inwardly bent arms terminating in short distances from each other, bands connecting the free ends of the arms of each spring to the arms of the remaining springs, strips of fibrous material secured to the arms of the respective springs, and a resilient tread carried by the arms of the springs and provided with a central rib which is interposed between said arms.

696,876. BROILER OR TOASTER. HENRY E. LYNN, Pittsburgh, Pa. Filed July 30, 1901. Serial No. 62,894. (No model.)

Claim.—1. A broiler and toaster comprising a receptacle closed at one side and open at the other, a trough arranged at one end of the receptacle, a detachable grid for the open side of the receptacle adapted to have one end inserted in the trough, and a bell for covering the opposite or free end of the grid to the receptacle.

2. A broiler and toaster comprising a receptacle provided at its lower end with a drain-trough, a detachable grid for closing the open side of the receptacle, a bell pivotally connected to the grid and adapted to secure the same to the receptacle, and feet at one end of the receptacle for supporting the same in front of a fireplace, said grid being offset intermediate its ends and made reversible so that either side may be presented toward the open side of the receptacle.

3. A broiler and toaster comprising a receptacle, supporting-foot arranged at one end thereof, a detachable grid for covering the open side of the receptacle, means for securing said grid to the receptacle, and a handle on the receptacle provided with a socket to receive a suitable prop or brace.

4. A broiler and toaster comprising a receptacle, a reversible grid for covering the open side of the receptacle, feet for supporting the receptacle in a substantially vertical position in front of a fireplace, a handle on the receptacle provided with a socket adapted to receive a suitable brace or prop, and a pivoted bell on the grid adapted to engage a pin or stud on the handle of the receptacle.

5. A broiler and toaster comprising a receptacle, means for holding said receptacle in a substantially vertical position in front of a fireplace, a drain-trough at the lower end of the receptacle, a detachable grid for closing the open side of the receptacle, and a detachable guard adapted to extend across the lower portion of the receptacle and cover the drain-trough.

696,877. APPARATUS FOR PRODUCING REPEAT-DESIGNS. HARRY MACKINTOSH, Glasgow, England. Filed Sept. 14, 1900. Serial No. 32,122. (No model.)

Claim.—1. An apparatus for designing patterns, comprising a transparent support for objects from which the pattern is to be produced, a series of adjustable lenses means for supporting them in a plane parallel to the support of the said objects a screen for receiving the images of the said objects and means for throwing rays of light on the objects, so that their forms will be cast by the lenses upon the said image-receiving means for describing the result of the arrangement of the said objects, substantially as described.

2. The combination of a lantern, a plate to carry objects which are to form the pattern, a mirror reflecting the rays from the lantern onto said plate, a series of lenses in one plane, a plate at the focus of these lenses to receive the images, and means for adjusting the position of the lenses whereby the various images can be made to exactly register with each other as repeats.

3. An apparatus for producing various designs, comprising an object-support, means for rotating the object-support for varying the position of the said objects in the apparatus, a lens frame or support arranged in a plane parallel with the object-support, means for turning the said lens-support and a screen for collecting the outlines of the objects projecting through the said lenses, together with means for passing rays of light through the object-plate and the lenses, the whole structure being such that the objects may be arranged and rearranged and the lenses varied in their position until a desirable pattern is shown upon the screen, substantially as described.

4. In an apparatus for throwing a series of repeat reflections upon a screen, the combination of a series of lenses, a wheel carrying these lenses, and means for rotating that wheel, substantially as described.

5. An apparatus for throwing a series of repeat reflections upon a screen, comprising an object-support and a lens-support, supporting-arms for holding the object-support adjustably in position, means for rotating all the screws simultaneously, whereby the said object-support can be moved to various places parallel with the lens-support and a screen for collecting the forms projected by the said objects to determine the style of design they will produce, substantially as described.

6. An apparatus for reflecting a series of images for determining certain designs, comprising a casing, an object-support mounted therein, screws engaging the said support, means for operating the screws simultaneously, a lens-support mounted above the object-support, screws engaging the said lens-support and means for operating them simultaneously, the structure being such that the object-support and the lens-support can be moved to different horizontal planes which are always parallel with each other for properly projecting the images produced by the said objects, substantially as described.

7. An apparatus for throwing a series of repeats on a screen, comprising an inclosing casing, a removable screen carried at the top thereof for collecting the images which are to produce the design, a lens-support and an object-support both adjustably mounted in the said casing, means for passing rays of light through the said casing, comprising a lamp or lantern and an inclined mirror and means for adjusting the relative position of the objects and the lenses until the desired design is produced upon the screen, substantially as described.

8. In an apparatus for throwing a series of repeat-images onto a screen, the combination of a series of similar lenses, two series of slides crossing each other at right angles on planes parallel with each other, and holding these lenses whereby the lenses can be adjusted in both directions so as not to overlap.

9. In an apparatus for throwing a series of repeat-images onto a screen, the combination with a series of similar lenses, two series of slides crossing each other at right angles and holding these lenses whereby the lenses can be adjusted in both directions so as not to overlap, of a series of blades arranged above the inner edges of the slides cutting off the light between the lenses when these latter are spread out wide.

10. In an apparatus for throwing a series of repeat-patterns onto a screen, the combination of a series of lenses arranged in parallel movable slides, the center one being capable of being slid backward and forward while the side ones are stationary, whereby the exact amount of drop required in drop-patterns can be made in the repeats and thus a correct repeat of a drop-pattern made.

696,878. METHOD OF GAGING TEMPERATURES OF HEATED SUBSTANCES. EVERETT F. MOORE, Trumbull, N. Y. Filed Aug. 4, 1906. Serial No. 726,191. (No specimens.)

Claim.—1. The method of gaging the temperature of a material which becomes incandescent when heated, consisting in comparing said material heated to a luminous state with an optical standard, said comparison being made by placing said material and standard so that at least a portion of one is in the path of the rays passing from the other to the eye, observing the standard and material and noting if the one merges in the other to such a degree as to indicate the correct temperature within the necessary limits.

2. The method of gaging the temperature of a material which becomes incandescent when heated, consisting in comparing said material heated to a luminous state with an optical standard, said comparison being made by placing said material and standard so that at least a portion of one is in the path of the rays passing from the other to the eye and varying the degree of heat until the color of one merges in that of the other.

3. The method of gaging the temperature of a material which becomes incandescent when heated, consisting in comparing said material heated to a luminous state with an optical standard, said comparison being made by placing said material and standard so that at least a portion of the one is in the path of the rays passing from the other to the eye, not-

ing the difference in color between the two whereby it may be readily determined whether the temperature of the material is above or below that indicated by the standard, and increasing or decreasing the heat of the material until the one merges into the other whereby it can easily and at once, be detected when the material is at the desired temperature.

4. The method of gaging the temperature of a material which becomes incandescent when heated, consisting in comparing said material heated to a luminous state, with a standard placed in the path of the rays passing to the eye from said material so that a portion thereof is superposed upon the field of said material, and varying the temperature of the material so that that portion of the standard superposed may be made to merge into the field of said material, thereby showing that the desired temperature thereof has been reached.

5. The method of gaging the temperature of a substance when heated to incandescence, consisting in comparing the degree of incandescence of said substance with a standard which is incandescent simultaneously therewith and incandescent to a degree corresponding to the incandescence of said substance when heated to the desired temperature, said standard being located in the path of the rays passing from the heated substance to the eye.

6. The method of gaging the temperature of a material consisting in comparing it with an optical standard whose color and luminosity correspond to that resulting from a known degree of incandescence or temperature, said comparison being made by placing one of these in the rays passing to the eye from the other so that a portion at least of one will be superposed upon the field of the other, varying the temperature of the material whereby it may be made to agree in color and luminosity with that of the standard and the portion of the one superposed made to merge in the field of the other.

7. The method of determining the temperature of an incandescent substance consisting in placing in the path of the rays passing from the incandescent substance to the eye an incandescent standard and changing the degree of incandescence of said standard until it becomes practically identical with the incandescence of said substance.

696,879. PLAYING-BALL. FRANK H. REHMAN, Hartford, Conn., assignor to the Knapshall Manufacturing Company, a Corporation of New Jersey. Filed Mar. 4, 1908. Serial No. 56,735. (No model.)

Claim.—1. A ball comprising a whole hollow rubber sphere in a state of expansion upon a solid core of gutta-percha, and a cover of leather or fabric upon said sphere.

2. A ball comprising an integral hollow rubber sphere in a state of expansion upon a solid core, and a leather cover upon said sphere.

3. A ball comprising an integral sphere of rubber expanded over a solid and relatively hard filling formed from plastic material and a stitched leather cover upon said sphere.

4. A ball consisting of a whole thick spherical India-rubber sphere, in a state of expansion over a solid sphere of gutta-percha and a leather cover stretched over said India-rubber sphere.

5. A ball comprising a whole sphere of firm India-rubber in a state of expansion over a solid sphere of gutta-percha, the diameter of the core being more than one-half that of said sphere, and a leather cover upon said sphere.

6. A ball consisting of a core formed of plastic material within a softer elastic sphere and holding the latter under tension, and a cover consisting of pliable fibrous material.

696,880. TRACTION SYSTEM. FRANK J. SPRAGUE, New York, N. Y., assignor to the Sprague Electric Company, a Corporation of New Jersey. Filed Dec. 14, 1906. Serial No. 696,464. (No model.)

Claim.—1. In an electrical train system, the combination of translating devices, circuits therefor, a governing train-line independent of the other circuits provided with two pairs of controlling-wires, and means for closing circuits through a wire of one pair and a wire of the other pair simultaneously, substantially as described.

2. In an electrical train system, the combination of translating devices, circuits therefor, a governing train-line independent of the other circuits provided with two pairs of controlling-wires, means for closing circuits through one of the wires of one pair and a wire of the other pair

simultaneously, and means for closing circuits through the other wire of the first pair and one of the wires of the second pair simultaneously, substantially as described.

3. In an electrical train system, the combination of translating device, circuits therefor, a governing train-line independent of the other circuits provided with two pairs of controlling-wires, means for closing circuits through one of the wires of one pair and either of the wires of the other pair simultaneously, and means for closing circuits through the other wire of the first pair and one of the wires of the second pair simultaneously, substantially as described.

4. In a system of secondary motor control, the combination of two pairs of conductors, motor-controlling means controlled by these four conductors, and means for connecting in series in a circuit either conductor of one pair with either conductor of the other pair, substantially as described.

5. In a system of secondary motor control, the combination of two pairs of conductors, motor-controlling means controlled by these four conductors, means for connecting either conductor of one pair in series with either conductor of the other pair, and means for preventing the simultaneous connection in circuit of the two conductors of one pair, substantially as described.

6. In a system of secondary motor control, the combination of two pairs of conductors, motor-controlling means controlled by these four conductors, the two conductors of each pair being normally open at one end, means for connecting in a circuit either conductor in one pair in series with either conductor in the other pair, and means for preventing the simultaneous closure through the conductor of one pair and both of the conductors of the other pair, substantially as described.

7. In a system of secondary motor control, the combination with a pair of motor-reversing wires and a pair of motor-grouping wires, of means for connecting either wire of one pair in a circuit in series with either wire of the other pair, substantially as described.

8. In a system of secondary motor control, the combination of a pair of motor-reversing wires and a pair of motor-grouping wires, means for connecting either wire of one pair in series with either wire of the other pair, and means governed by the closure of a circuit through a reversing and motor-grouping wire for preventing simultaneous connection of the two grouping-wires with a reversing-wire, substantially as described.

9. In a system of secondary motor control, the combination of a pair of motor-reversing wires and a pair of wires for effecting series and multiple relations, respectively, of the motor, either of which motor-reversing wires may be connected with either of the motor-grouping wires for effecting desired grouping of the motor, and means for determining circuit connections consisting of two parts, one of the parts for selecting the one or the other of the direction-controlling wires, and the other part for selecting the motor-grouping wire to be placed in series therewith, substantially as described.

10. In an electrical train system, the combination of a plurality of

motor equipments, governing devices for grouping the motor in each equipment in series and multiple relation, and a train-line containing two wires for controlling the direction of motor movement, either of which wires may be connected with either of the motor-grouping devices for effecting the desired grouping of the motor, substantially as described.

11. In an electrical train system, the combination of a plurality of motor equipments, governing devices for grouping the motor in each equipment in series and multiple relation, and a train-line containing two wires for controlling the direction of motor movement, either of which wires may be connected with either of the motor-grouping devices for effecting the desired grouping of the motor, and a circuit-changer for determining circuit connections, substantially as described.

12. In an electrical train system, the combination of a plurality of motor equipments, governing devices for grouping the motor in each equipment in series and multiple relation, a train-line containing two wires for controlling the direction of motor movement, either of which wires may be connected with either of the grouping devices for effecting the desired groupings of the motor, and means for determining circuit connections consisting of two parts, one of the parts for selecting the one or the other of the direction-controlling wires, and the other part for selecting the motor-grouping device to be energized, substantially as described.

13. In a system of secondary motor control, the combination of coils for effecting reversal of the motor, coils for effecting grouping of the motor in series and multiple relation, two controlling-wires, each of which energizes a reverser-coil and one or other of the grouping-coils, and a circuit-changer for selecting which of the grouping-coils shall be energized, substantially as described.

14. In a system of secondary motor control, the combination of coils for effecting a reversal of the motor and coils for effecting grouping of the motor in series and multiple relation, two controlling-wires, each of which energizes a reverser-coil and one or other of the motor-grouping coils, and means for determining circuit connections consisting of two independent parts, one of the parts for selecting the reverser-coil, and the other part for selecting the motor-grouping coil to be energized, substantially as described.

15. The combination of a current-varying controller, which comprises a resistance-controller and means for determining circuit connections, these parts being independently movable, means moving with each part for operating the controller, and means for securing co-operative action of the parts of the controller, substantially as described.

16. The combination of a current-varying controller, which comprises a resistance and means for determining circuit connections, means for operating the controller, and a circuit-interrupter to secure co-operative action of the parts of the controller, substantially as described.

17. The combination of a current-varying controller, which comprises a resistance, and means for determining circuit connections, means for operating each of these parts of the controller, and a circuit-interrupter to secure the co-operation of the parts of the controller, the circuit-interrupter being driven with one of the parts of the controller, substantially as described.

18. The combination of a current-varying controller, which comprises a rheostat, and means for determining circuit connections, means for operating each of these parts, and a circuit-interrupter to secure co-operation of the above-named parts of the controller, the circuit-interrupter being operated with the rheostat, substantially as described.

19. In an electrical train system, the combination of a motor equipment, a controller therefor having reversing, rheostatic and series-multiple grouping parts, and an independent governing-line having two sets of controlling-wires, one for controlling the reversing and motor-grouping parts of the controller and the other for controlling the rheostatic part thereof, substantially as described.

20. In an electrical train system, the combination of a motor equipment, a controller therefor having reversing, rheostatic and series-multiple grouping parts, and an independent governing-line, having two sets of controlling-wires for the controller, one set for closing the circuit of the motor through the reversing and motor-grouping parts of the controller with resistance in the motor-circuit, and the other set for varying the resistance in the motor-circuit, substantially as described.

21. In an electrical train system, the combination of a motor equipment, governing devices for reversing and for grouping the motor in series and multiple relation and for effecting changes in the resistance of the motor-circuit, a governing-line containing two independent sets of wires, one set for effecting variations in resistance in the motor-circuit, and two of the wires of the other set for controlling the direction of motor movement, either of which directional wires may be connected with either of the grouping devices for effecting the desired grouping of the motor, and a circuit-changer for determining the circuit connections, substantially as described.

22. In an electrical train system, the combination of a motor equipment, governing devices for grouping the motor in series and multiple relation, and for effecting changes in the resistance of the motor-circuit,

and a train-line containing two independent sets of wires for controlling the governing device, two of the wires of one set being directional wires for controlling the direction of motor movement, either of which may be connected with either of the grouping devices for effecting the desired grouping of the motors, and means for determining circuit connections consisting of two independent parts, one of the parts for selecting the one or the other of the direction-controlling wires and the other part for selecting the motor-grouping device and effecting variation in resistance, substantially as described.

22. In a system of secondary motor control the combination of a motor equipment, a controller therefor consisting of reversing, series-multiple and rheostatic parts and a governing train-line for the controller consisting of two sets of wires, one set for closing circuit to the motors through the reverser and series-parallel parts of the controller and a full resistance, and the other set for varying the resistance, substantially as described.

24. In a system of secondary motor control, the combination of a motor equipment, a controller therefor having coils for effecting grouping of the motors in series and multiple relation respectively and means for effecting changes of resistance in the motor-circuit, and a governing-line having three sets of controlling-wires therein, one set for controlling the direction of rotation of the motors and energizing the series and multiple coils, another set for determining which of the series and multiple coils shall be energized, and a third and independent set for controlling the resistance in the motor-circuit, substantially as described.

25. In an electrical train system, the combination of motor equipments, controllers therefor having switches for establishing series and parallel relation of the motors and circuit-breakers in series therewith, and a controlling-circuit common to the grouping-switches and the circuit-breakers, substantially as described.

26. In an electrical train system the combination of motor equipments, controllers therefor having motor-grouping switches for establishing series and multiple relation of the motors, and circuit-breakers in series therewith, a controlling-circuit common to the grouping-switches and the circuit-breakers, and an independent controlling-circuit for effecting variations in the resistance in the motor-circuits, substantially as described.

27. In a system of secondary motor control, the combination of a motor-controller having separably-movable reversing, grouping and rheostatic parts, and a train-line having direction-controlling wires and speed-controlling wires, the direction-controlling wires also energizing the motor-grouping parts of the controller for effecting grouping of the motors, and the speed-controlling wires determining the grouping of the motors and the resistance of the motor-circuit, substantially as described.

28. In a train with equipped cars, the combination of a pair of motor-reversing wires and a pair of motor-grouping wires for each car, and means, including an independent governing train-line, for connecting either wire of one pair on each car in series with either wire of the other pair on the same car, substantially as described.

29. In a train with equipped cars, the combination on each equipped car of motors, a controller individualized as to each car for reversing the motors and for grouping them in series and parallel relation, and a governing train-line containing two wires for controlling the direction of motor movements, either of which may be connected with either of the motor-grouping devices for effecting the desired grouping of the motors, substantially as described.

30. In a train with equipped cars, the combination of motors on each equipped car, a controller individualized as to each car, having separably-movable reversing, rheostatic, and series-multiple grouping parts, and an independent governing train-line having two sets of controlling-wires, one set for controlling the reversing and motor grouping parts of each controller, and the other set for controlling the rheostatic part of each controller, substantially as described.

31. In an electrical train system, the combination of motor-equipments, controllers therefor comprising circuit-breakers and switches for grouping the motors in series and multiple relation, actuating-coils for the grouping-switches, and a controlling-circuit for the circuit-breakers including therein either the series or multiple actuating-coils, and contacts in the controlling-circuits controlled by the current therethrough, substantially as described.

32. The combination of a current-varying controller, which comprises a resistance and means for determining circuit connections, means for operating each of these means including a pilot-motor for operating the resistance, and a circuit-interrupter to secure the cooperation of the above-named parts of the controller, the circuit-interrupter being driven by the pilot-motor, substantially as described.

33. The combination of a motor equipment, a current-varying controller therefor which comprises a resistance-controller and means for determining the connections of the motor equipment, these parts being independently movable, means for operating each of these parts of the controller, and means moving with each part for securing coöperative action of the parts of the controller, substantially as described.

34. The combination of a motor equipment, a current-varying controller therefor which comprises a resistance and means for determining the connections of motor equipment, means for operating each of these parts of the controller, and a circuit-interrupter for securing coöperative action of the parts of the controller, substantially as described.

35. The combination of a motor equipment, a current-varying controller therefor which comprises a resistance and means for determining the connections of the motor equipment, means for operating each of these parts of the controller, and a circuit-interrupter for securing coöperation of the parts of the controller, the circuit-interrupter being driven with one of the parts of the controller, substantially as described.

36. The combination of a motor equipment, current-varying controllers therefor which comprise a resistance and means for determining the connections of the motor equipment, means for operating each of these parts of the controller, including a pilot-motor, and a circuit-interrupter for securing coöperation of the parts of the controller, the circuit-interrupter being driven by the pilot-motor, substantially as described.

37. A train system comprising a plurality of motor equipments, current-varying controllers therefor, which include a resistance and means for determining circuit connections for each motor equipment, these parts being independently movable, means for operating the parts of each controller, and means for securing coöperative action of the parts of each controller, substantially as described.

38. A train system comprising a plurality of motor equipments, current-varying controllers therefor, which include a resistance and means for determining circuit connections for each motor equipment, these parts being independently movable, means for operating the parts of each controller, and means for securing coöperative action of the parts of all of the controllers, substantially as described.

39. A train system comprising a plurality of motor equipments, current-varying controllers therefor, which include a resistance and means for determining the connections for each motor equipment, means for operating these parts of each controller, and a circuit-interrupter for securing coöperative action of the parts of each controller, substantially as described.

40. A train system comprising a plurality of motor equipments, current-varying controllers therefor, which include a resistance and means for determining the connections for each motor equipment, means for operating each of these parts of each controller, and a circuit-interrupter for securing coöperative action of the parts of each controller, the circuit-interrupter being driven with one of the controllers, substantially as described.

41. A train system comprising a plurality of motor equipments, current-varying controllers therefor including a resistance and means for determining the connections for each motor equipment, means for operating each of these parts of each controller, including a pilot-motor, and a circuit-interrupter for securing coöperation of the parts of the controller, the circuit-interrupter being driven by the pilot-motor, substantially as described.

42. The combination of a motor equipment, a current-varying controller therefor which comprises a resistance and means for determining the circuit connection of the equipment, means for operating these parts of the controller, including a pilot-motor for operating the resistance, and a circuit-interrupter driven by the pilot-motor for securing coöperative action of the parts of the controller, substantially as described.

43. The combination of a rheostat, a switch for operating it, means independent of the switch for interrupting the movement of the rheostat at a plurality of definite running positions, and means for opening the circuit while the rheostat is passing from one definite position to another, substantially as described.

44. The combination of a rheostat and a series-multiple switch, means for setting the series-multiple switch for series connection, means for cutting out the resistance of the rheostat, means for opening the circuit, means for throwing in resistance at the rheostat, and means for closing the series-multiple switch for multiple connection, substantially as described.

45. The combination of a rheostat and a series-multiple switch, means for setting the series-multiple switch for series connection, means for cutting out the resistance of the rheostat, means for opening the series-multiple switch, means for throwing in resistance in the circuit, and means for closing the series-multiple switch for multiple connection, substantially as described.

46. The combination of a rheostat and a series-multiple switch, means for setting the series-multiple switch for series connection, means for cutting out the resistance of the rheostat and automatically stopping it, means for opening the circuit, means for throwing in resistance at the rheostat, and means for closing the series-multiple switch for multiple connection, substantially as described.

47. The combination of a rheostat and a series-multiple switch, means for setting the series-multiple switch for series connection, means for cutting out the resistance of the rheostat and automatically stopping

it, means for opening the series-multiple switch, means for throwing in resistance at the rheostat, and means for closing the series-multiple switch for multiple connection, substantially as described.

48. The combination of a rheostat and a series-multiple switch, a switch for operating them, means independent of the switch for interrupting the movement of the rheostat at a plurality of definite positions, and means for opening the circuit at the series-multiple switch while the rheostat is passing from one definite position to another position, substantially as described.

49. The combination of a rheostat, a switch for operating it, means independent of the switch for interrupting the movement of the rheostat at a definite position, means for starting the rheostat again in the same direction by operation of the switch, means independent of the switch for opening the circuit while the rheostat is passing to another position, and means independent of the switch for again interrupting the movement of the controller at second definite position, substantially as described.

50. The combination of a current-varying controller comprising a rheostat and a series-multiple switch, means for moving the rheostat at will from one limit to another, means for moving the rheostat to a definite intermediate position and automatically stopping it there, means for continuing the movement of the rheostat in the same direction to its limit, and means for opening the circuit controlled by the controller at the controller while it is passing from the intermediate position to its limiting position, substantially as described.

51. A rheostat provided with a movable member, electrically-actuated mechanism for moving it to any one of a plurality of definite current-varying positions, and for maintaining it in the position to which it may be moved, and means for restoring it to opening position, all movements being in the same direction, substantially as described.

52. A rheostat provided with contacts, a cylinder, electrically-actuated mechanism for moving it to any one of a plurality of definite current-varying positions and for maintaining it in the position to which it may be moved, and for restoring it to open position, all movements being in the same direction, substantially as described.

53. The combination of a current-varying controller provided with a movable cylinder and means electrically controlled for effecting movement of the controller to one or more definite running positions, and for effecting movement of the controller in the same direction to release or off position, substantially as described.

54. The combination of a plurality of motor or motor equipments, current-varying controllers therefor, a suitable circuit, means electrically controlled thereby for effecting advance movement of the controllers in one direction to definite running positions or to release or off position, substantially as described.

55. The combination of a motor, a controller therefor, an operator's switch, means connected therewith for operating the controller from its initial position, and means independent of the operator's switch for restoring the controller to initial position by further movement in the same direction, substantially as described.

56. The combination of one or more operator's switches, each provided with a plurality of contacts, one or more motor equipments and circuits and current-varying controllers therefor, a plurality of sets of contacts on each of the controllers, means for closing each of the controllers at one set of contacts by closing the operator's switch at one of its contacts, means for opening the circuit at each controller, and then closing the controller at another set of contacts by closing the operator's switch at another of its contacts, substantially as described.

57. The combination of one or more operator's switches, each provided with a plurality of contacts, one or more motor equipments and circuits and current-varying controllers therefor, a plurality of sets of contacts on each of the controllers, means for closing each of the controllers at one set of contacts by closing the operator's switch at one of its contacts, means for opening the circuit at each controller and then closing the controller at another set of contacts by closing the operator's switch at another of its contacts, and means for automatically holding the controller at the different sets of contacts, substantially as described.

58. The combination of a motor to drive a car, a suitable system of circuits for operating the motor, including a current-varying controller which embraces a rheostat, pilot mechanism for the controller, connections for operating the pilot mechanism which cause increased speed of the motor, and connections operated by the current-varying controller for operating the pilot mechanism to restore the rheostat to initial or off position, substantially as described.

59. The combination of motor to drive a car, a suitable system for operating the motor, including a current-varying controller which embraces a rheostat, reverser-switch and series-multiple switch, pilot mechanism for the rheostat, connections for operating the pilot mechanism to cause increase of speed of the motor, and connections operated by the current-varying controller for operating the pilot mechanism to restore the rheostat to initial or off position, substantially as described.

60. A train with cars individually equipped with motor and current-varying controllers including a rheostat, an operator's switch for operating the same, means including contacts in the controller for restoring the rheostat to initial position independently of the operator's switch, substantially as described.

61. The combination of a rheostat, a series-multiple switch and a reverser-switch, each separately movable, means for operating these parts, and a switch for securing coöperative action thereof, substantially as described.

62. The combination of a rheostat, a reverser-switch and a series-multiple switch, means for operating these parts, and a circuit-changer for securing coöperative action thereof, substantially as described.

63. The combination of a rheostat, a reverser-switch and series-multiple switch, means for operating these parts, and a circuit-interrupter driven with the rheostat for securing coöperative action of the parts, substantially as described.

64. The combination of a rheostat, a series-multiple switch, a reverser-switch, means for operating these parts, including pilot mechanisms for operating the rheostat, and a circuit-interrupter operated by the pilot-motor, for securing coöperative action of these parts, substantially as described.

65. The combination of a rheostat, a reverser-switch and a series-multiple switch, a pilot-motor for operating the rheostat, a circuit-interrupter operated by the pilot-motor and including a limit-switch therefor, for securing coöperative action of the rheostat, reverser-switch and series-multiple switch, substantially as described.

66. The combination of a rheostat, a reverser-switch and a series-multiple switch, means for closing the reverser-switch and series-multiple switch for series connection in either direction, means for cutting out the resistance of the rheostat, means for opening the series-multiple switch and reverser-switch, means for throwing in resistance of the rheostat, and means for closing the series-multiple switch and the reverser-switch, for multiple connection in the same direction, substantially as described.

67. The combination of a plurality of cars, driving-motors therefor and circuits for the motor, a relay train-circuit, rheostats, series-multiple and reverser switches for the motor operated through the relay-circuit, and means for opening the motor-circuits at the reverser and series-multiple switches upon the current being cut off from the relay-circuit, substantially as described.

68. The combination of a motor, a motor-circuit, a rheostat for the motor, an operator's switch or master-controller for operating the rheostat through an independent governing-circuit to advance it to different running positions, means automatically operated for opening the motor-circuit independently of the rheostat, and means for restoring the rheostat by movement in the same direction as above, toward or to off position, independently of the operator's switch or master-controller, substantially as described.

69. The combination of motor, motor-circuits, rheostats for the motor, and a governing-circuit independent of the motor-circuits for operating the rheostats to advance them to different running positions, means automatically operated for opening the motor-circuits independently of the rheostats, and means for automatically restoring the rheostats toward or to off position by movement in the same direction as above, substantially as described.

70. A train with two or more individually-equipped cars and means on each car for controlling all of the cars simultaneously, a reverser-switch, a series-multiple switch and a rheostat, and means including contacts on the reverser-switch and the series-multiple switch for restoring the rheostat to release or off position upon the opening of the circuit, substantially as described.

71. A train with cars individually equipped with motor, a rheostat, a reverser-switch and series-multiple switch, a switch for operating the same, means including contacts in the reverser-switch and series-multiple switch for restoring the rheostat to initial position independently of the operator's switch, upon the opening of the circuit, substantially as described.

72. The combination of main circuits, rheostats therein, a governing-line, one or more operator's switches connected therewith, means for advancing the rheostats to different running positions, means for opening the train-line, relay mechanisms connected therewith for opening the main circuits, means for automatically restoring the rheostats toward or to off position by movement in the same direction as above, and means for preventing the closure of the main circuits or train-line after the opening thereof, until the rheostats have been restored toward or to off position, substantially as described.

73. The combination of main circuits, rheostats therein, a governing train-line, one or more operator's switches connected therewith, means for advancing the rheostats to different running positions, means for opening the train-line, relay mechanisms connected therewith for opening the main circuits, means for automatically restoring the rheostats toward or to off position by movement in the same direction as above, and means for pre-

venting the closure of the train-line or main circuits and the further advance of the rheostats until the rheostats are restored toward or to off position, substantially as described.

74. The combination of a motor, a motor-circuit, a current-varying controller for the motor, an operator's switch and circuit for operating the controller, means for opening the motor-circuit in the controller, means for restoring the controller toward or to off position independently of the operator's switch, and a cut-out switch connected with the controller and closed in certain positions thereof, which, when the controller has been restored to open position, restores control of the controller to the operator's switch, substantially as described.

75. The combination of a governing circuit one or more operator's switches connected therewith, a current-varying controller or controllers, means controlled from each operator's switch through the governing-circuit for operating the controller or controllers, means for opening the main circuits at the controllers immediately upon opening the operator's switch, means for restoring the controller or controllers to initial or off position, irrespective of further movement of the operator's switch, and means for restoring control of each controller to the operator's switch when the controller has been restored to initial or off position, substantially as described.

76. The combination of a governing train-line, one or more operator's switches connected therewith, a current-varying controller or controllers, means controlled from each operator's switch through the governing train-line for operating the controller or controllers, means for opening the main-motor circuits at the controllers immediately upon opening the operator's switch, means for restoring the controllers to initial or off position, irrespective of further movement of the operator's switch, means for restoring control of each controller to the operator's switch when each controller has been restored to its initial position, substantially as described.

77. The combination of motors, motor-circuits and current-varying controllers for the motors, one or more operator's switches, and a circuit for operating the controllers, means for opening the motor-circuits at the controllers, means for restoring the controllers independently of the operator's switches to initial or off position, and cut-out switches connected with the controllers and closed in certain positions thereof, which when closed restore control of the controllers to the operator's switches, substantially as described.

78. The combination of a motor, a rheostat, a series-multiple switch and a reverser-switch, a circuit through which these parts are operated, a cut-out switch, which is included in the circuit for operating them in a definite position or positions of the rheostat, and a shunt around the cut-out switch through the controller and reverser, which is closed in certain definite positions of these parts, substantially as described.

79. A car equipped with a motor to drive it, an electrically-operated current-varying controller and reverser for the motor, a train-line made up of two distinct pairs of wires, and reversible train connections for the train-line, substantially as described.

80. A car provided with an independent governing-line containing a pair of direction-controlling wires which terminate in similar groups at each end of the car, the terminals of the wires in the group at one end being exchanged, as compared with their terminals in the group at the other end, and a pair of speed-controlling wires which terminate in similar groups at each end of the car without being so exchanged, substantially as described.

81. A car provided with a motor or motors, current-varying controllers and reverser therefor, a relay or governing circuit for said controllers and reverser having a pair of direction-controlling and a pair of speed-controlling wires terminating in similar groups at each end of the car, the terminals of the direction-controlling wires in the group at one end being exchanged, as compared with their terminals in the group at the other end, substantially as described.

82. A car provided with a pair of speed-controlling wires, and a pair of direction-controlling wires, which terminate in similar groups at each end of the car, the terminals of the direction-controlling wires in the group at one end being exchanged, as compared with their terminals in the group at the other end, and the terminals of the speed-controlling wires corresponding in position at both ends, substantially as described.

83. A train consisting of interchangeable cars, each of which is provided with a pair of direction-controlling wires, which terminate in similar groups at each end of each car, the terminals of the wires in the group at one end being exchanged, as compared with the terminals in the group at the other end, and a pair of speed-controlling wires, the terminals of the speed-controlling wires corresponding at both ends, and means for connecting like direction-controlling wires and like speed-controlling wires at the abutting ends of the car, substantially as described.

84. In a car equipped with a plurality of motors, the combination of a controller therefor having motor-reversing, motor-grouping, and rheostatic parts, and a controlling-line having direction-controlling wires and speed-controlling wires, the direction-controlling wires also extending the

motor-grouping parts of the controller for affecting series and multiple relation of the motors, and the speed-controlling wires determining the grouping of the motors and resistance of the motor-circuit, the direction-controlling wires terminating at similar groups at each end of the car, and the terminals of the wires in the group at one end being exchanged as compared with their terminals at the other end, and the speed-controlling wires terminating in similar groups at each end of the car, without being exchanged, substantially as described.

85. In an electrical train system, the combination of translating devices and circuits therefor, one or more reverser-switches, and one or more series-multiple switches in the circuits, and a governing train-line with two sets of train-wires, a circuit-interrupter, means for controlling the reverser and series-parallel switches connected with the first set of train-wires, and means for controlling the circuit-interrupter connected with the second set of train-wires, substantially as described.

86. In an electrical train system, the combination of translating devices and circuits therefor, one or more reverser-switches and series-multiple switches, and one or more rheostats to be operated in conjunction with the switches, a governing train-line having two sets of train-wires, a circuit-interrupter, means for controlling the reverser-switches and series-multiple switches connected with one set of train-wires, and means for controlling the circuit-interrupters and rheostats connected with the other set of train-wires, substantially as described.

87. The combination of a series-multiple switch and a reverser-switch each having a normal open-circuit off position, and means for moving these switches independently of each other, in the same or in opposite directions to each other, substantially as described.

88. The combination of a series-multiple switch and a reverser-switch, the series-multiple switch having a normal circuit off position intermediate its positions for placing the circuit in series and multiple, and means for moving the two switches in the same or in opposite directions at will, substantially as described.

89. The combination of a rheostat-cylinder, a pilot-motor for operating it, limit-switches for the pilot-motor operated with the cylinder, and a circuit-interrupter, also operated with the cylinder, substantially as described.

90. The combination of a circuit-changing device, a series motor, and a permanent shunt around the field-coil of the series motor for the purpose of holding the field and reducing the arc in breaking, substantially as described.

91. The combination of a circuit-changing device, a series motor with laminated field and a permanent shunt around the field-coil of the motor for holding the field and reducing the arc in breaking, substantially as described.

92. The combination of a pair of series motors, a series-multiple switch therefor, means for breaking the circuit in passing from series to multiple without the introduction of resistance, and a permanent shunt around the field-coil for each of the motors for the purpose of holding the field and reducing the arc in breaking, substantially as described.

93. The combination of an operator's switch, a train-line and a car system, and switches whereby all of them can be connected together, and any one be disconnected without disconnecting the others, substantially as described.

94. In a train system, the combination of a train-line and car system, the train-line being made up of a plurality of wires and the car system being connected to the train-line in multiple to each other, a current-varying controller in each car system, means operated through different wires of the train system for bringing all of the controllers to two definite positions other than the open position, the line connection when one of the wires is operated being made through a relay, substantially as described.

95. In a system of secondary motor control, the combination of motors, coils for effecting reversal of the motors, coils for effecting grouping of the motors in series or multiple relation, two controlling-wires each of which energizes a reverser-coil and one or other of the grouping-coils, a circuit-changer for selecting which of the grouping-coils shall be energized, and a throttle which controls the movement of the circuit-changer, substantially as described.

96. In the system of secondary motor control, the combination of motors, coils for effecting reversal of the motors and coils for effecting grouping of the motors in series and multiple relation, two controlling-wires, each of which energizes a reverser-coil and one or other of the motor-grouping coils, means for determining the circuit connections consisting of two independent parts, one of the parts for selecting the reverser-coil and the other part for selecting the motor-grouping coil to be energized, and a throttle which controls the movement of the last-named part, substantially as described.

97. In a system of secondary motor control, the combination of motors, a main motor-circuit, reversing and grouping switches for the motors, actuating-coils for both the reversing and grouping switches, and a con-

trolling-circuit including in series an actuating-coil for each of these switches, and maintained through contacts controlled by the reversing-switch, substantially as described.

98. In a system of secondary motor control, the combination of motor, a main motor-circuit, reversing and grouping switches for the motor, actuating-coils for both the reversing and grouping switches, and a controlling-circuit including in series an actuating-coil for each of these switches, and maintained through contacts controlled by the grouping-switch, substantially as described.

99. In a system of secondary motor control, the combination of motor, a main motor-circuit, reversing and grouping switches for the motor, actuating-coils for both the reversing and grouping switches, and a controlling-circuit including in series an actuating-coil for each of these switches, and maintained through contacts controlled by the reversing and grouping switches, substantially as described.

696,881. WIRE-STRETCHER. JAMES A. WALLS and ROBERT L. BOTTEN, Inventors. Filed July 8, 1901. Serial No. 67,314. (No model.)

Claim.—1. A wire-stretcher comprising a frame, a shaft mounted in the frame and provided with a winding-drum and means for rotating it, said frame having a stud, and a chain having connection with the frame having a hook for engagement with a post and adapted to be passed around the post and to engage its links interchangeably with the stud, and a chain-section attached to the first chain and having a clip for engagement with a wire to be stretched.

2. A wire-stretcher comprising a frame adapted to rest against a post and having teeth for engagement therewith, a shaft mounted in the frame and projecting therebeyond, a winding-drum upon the shaft beyond the frame and having clutches for engagement with a wire, a ratchet upon the drum, a lever pivoted upon the shaft and having a pawl for engagement with the ratchet to rotate the drum, a retaining-pawl pivoted to the frame for engagement with the ratchet and having a rearwardly-directed foot, a spring disposed between the foot and frame to hold the pawl yieldably engaged with the ratchet, means for holding the frame against a post, a stud, and a chain having connection with the frame and having a hook for engagement with a post, said chain being adapted to be passed around the post and to engage its links interchangeably with the stud, and a chain-section attached to the first chain and having a clip for engagement with a wire to be stretched.

696,882. FLOODING REGENERATIVE HEATER FOR LIQUIDS. EDWARD ARLBERG, Inventor. Filed Dec. 30, 1901. Serial No. 58,857. (No model.)

Claim.—1. The combination with a heating-chamber, of a casing enclosing the same and spaced therefrom, a rotating drum having a circular wall arranged between said enclosing casing and said heating-chamber and spaced from both, means for causing the liquid to be treated to pass through said space between the heating-chamber and the drum and the enclosing casing and the drum, and means for causing the liquid to flow over the outer surface of the enclosing casing, substantially as set forth.

2. The combination of a steam heating-chamber, a rotating drum surrounding the same and spaced therefrom, an enclosing casing surrounding the drum and spaced therefrom, an air-chamber formed by said rotating drum and means for introducing the liquid to be treated into said air-chamber, substantially as set forth.

3. The combination of a heating-chamber, a rotating drum surrounding the same and spaced therefrom as to provide a space for the liquid to be treated, said drum having a head which forms beneath the same an air-compressing chamber, an enclosing casing surrounding said drum and spaced therefrom by a space for the liquid, means for introducing the liquid into said air-compressing chamber, and means for distributing the liquid to be treated over the outer surface of the enclosing casing, substantially as set forth.

4. The combination of a base, a heating-chamber supported thereby, a rotating drum surrounding said heating-chamber and spaced therefrom, said drum having a head which is spaced from the top of said heating-chamber and forms therewith an air-compressing chamber, an enclosing casing surrounding said drum and spaced therefrom, means for introducing the liquid to be treated into said air-compressing chamber, and a distributing-receptacle supported by said enclosing casing and which distributes the liquid to be treated over the outer surface of said enclosing casing, substantially as set forth.

5. The combination of a heating-chamber, a rotating drum surrounding the same and spaced therefrom, an enclosing casing surrounding said drum and spaced therefrom, said casing being provided with a corrugated circular wall, means for causing the liquid to pass through said space between the heating-chamber and the drum and between the enclosing casing and the drum, and means for causing the liquid to flow over the outer surface of said corrugated circular wall of the enclosing casing, substantially as set forth.

6. The combination of a heating-chamber having a cylindrical outer wall, a cylindrical drum enclosing said heating-chamber and spaced therefrom, means for rotating said drum, and an outer or enclosing chamber surrounding said rotating drum and spaced therefrom, said enclosing casing having a corrugated circular wall, means for introducing liquid to be treated into the space between said heating-chamber and the rotating drum and between the enclosing casing and the rotating drum, a distributing vessel supported by the upper part of said supporting-casing for distributing the liquid over the outer surface of said corrugated circular wall, and an annular trough surrounding the lower portion of the corrugated wall of said enclosing casing, substantially as set forth.

696,883. MACHINE FOR EXTRACTING LIQUID FROM BREWERS' GRAINS. DR. LEONARD ATWOOD, Philadelphia, Pa. Filed Dec. 6, 1900. Serial No. 36,908. (No model.)

Claim.—1. The combination in a machine for extracting liquid from brewers' grains, &c., of a hopper for the grain, means for feeding the grain in an even stream from the hopper, a porous endless carrying-belt upon which the grains are discharged, mechanism connected to the hopper constructed to mix liquid with the grains previous to their discharge upon said belt, so as to cause them to flow over the belt, and means for extracting liquid from the grains while on the belt, substantially as described.

2. The combination in a machine for extracting liquid from brewers' grains, &c., of an endless carrying-belt for the grains through which the liquid can escape, a pair of squeeze-rolls between which the belt is traversed, means for driving the squeeze-rolls and belt, a hopper mounted above the belt in front of the squeeze-rolls, mechanism connected to the hopper constructed to feed the grains from the hopper to the belt at a uniform speed, and to simultaneously add liquid to the grains so that they will flow evenly over the surface of the belt, substantially as described.

3. The combination in a machine for extracting liquid from brewers' grains, &c., of an endless belt, squeeze-rolls between which the belt passes, a hopper mounted above the belt, a feeding device connected to the hopper for delivering the grains in uniform quantity to the belt, and means for mixing liquid with the grains as they are fed to the belt so that they will be spread evenly over the face of the belt, substantially as described.

4. The combination in a machine for extracting liquid from brewers' grains, &c., of a porous belt, squeeze-rolls between which the belt passes, a hopper mounted above the belt, means for feeding the grains from the hopper onto the belt, and means for collecting the liquid extracted from the grains on the belt and at the squeeze-rolls, and mechanism connected to the hopper constructed to mix said liquid with the grains and to simul-

transmuted deliver them therefrom so that the extracted liquid is used for the purpose of floating the grain upon the surface of the belt, substantially as described.

3. The combination in a machine for extracting liquid from brewers' grain, *etc.*, of an endless porous belt, spaced-rolls between which the belt passes, a hopper mounted above the belt in advance of the spaced-rolls, a feeding device directly under the hopper consisting of two toothed rolls, the teeth of each roll being suitably spaced, and the teeth of one roll entering the space between the teeth of the other roll, said rolls being hollow and perforated, and a liquid-supply pipe connected to said rolls, so that the grain, as they are fed from the hopper, are mixed with sufficient liquid to cause them to be distributed in an even mass over the surface of the belt, substantially as described.

6. The combination in a machine for extracting liquid from brewers' grain, *etc.*, of a hopper, an endless porous belt, breast-rolls around which the belt passes, spaced-rolls between which the belt passes, a second belt overlapping the first-mentioned belt and passing around the upper spaced-roll and around a guide-roll, supporting-rolls for the belt where it receives the grain, collectors under the supporting-rolls and under the spaced-roll, a pump connected to the collectors, and a pipe leading from the pump to the hopper, substantially as described.

696,884. AUTOMATIC FIRE-EXTINGUISHER. WILLIAM BRY, Lowell, N. H., assignor to the Eddy Sprinkler Company, a Corporation of New Hampshire. Filed Jan. 25, 1902. Serial No. 460,576. (No model.)

Claim.—1. In an automatic fire-extinguisher, the combination with a water-supply pipe provided with a discharge-orifice and a valve-seat surrounding said orifice, of a valve for closing said orifice, a valve-support made in two parts secured together by a metal that will fuse at a low temperature, and a sprinkler-cap having its main body made con-

convex and provided at its outer edge with a flaring potted-like flange, and also having a series of oblique notches cut through its raised angular ridge and forming openings between the potted-like flange and the concave-convex portion of said cap, substantially as described.

2. In combination with the supply-pipe B, the stirrup-like casing A set in an opening in said pipe and provided with a discharge-orifice through its hub a, and with the seat b surrounding said orifice, the screw-stop f mounted adjustably in the hub c, the valve e, the mica disk d, the valve-support O made in two parts secured together by a metal that will fuse at a low temperature, and the concave-convex sprinkler-cap D provided with the potted-like flange A, the oblique notches K, and the openings i, substantially as described.

3. In an automatic fire-extinguisher, the concave-convex sprinkler-cap D provided with the flange A, the series of notches K, and the openings i, substantially as described.

4. In combination with a supply-pipe provided with a discharge-orifice, a seat surrounding said orifice, a valve for closing said orifice, a support for said valve, constructed and adapted to be disintegrated when the temperature of the room is raised above a predetermined point, and an adjustable stop for said support, of the concave-convex cap D provided with the flange A, the series of notches K, and openings i, loosely mounted upon a suitable bearing, and adapted to be reversed to present either its concave or convex side toward the outflowing jet of water, substantially as described.

696,885. IGNITION SYSTEM. FRED L. GIBSON, Chicago, Ill. Filed Dec. 5, 1901. Serial No. 54,587. (No model.)

Claim.—1. In an electric ignition system, the combination with a motor and make-and-break contact sparking device, of a dynamo operatively driven from said motor, an electric circuit extending from said dynamo through said sparking device, a second source of electric current, an alternative circuit extending from said second source through the sparking device, a power-impelled switch controlling according to position either of said circuits but tending to normally assume a position to open the second circuit, and means operable by the dynamo-current for automatically releasing said switch to open said second circuit.

2. In an electric ignition system, the combination with a motor and make-and-break contact sparking device, of a dynamo operatively driven from said motor, an electric circuit extending from said dynamo through said sparking device, a second source of electric current, an alternative circuit extending from said second source through the sparking device, a circuit-breaking device arranged to control said second circuit, and means operable by the dynamo-current for automatically throwing said circuit-breaking device into position to open said second circuit, said circuit-breaking device being constructed to remain in closed position after being operated by said automatic mechanism, for the purpose set forth.

3. In an electric ignition system, the combination with a motor and sparking device operated thereby, of a dynamo driven from said motor, an electric circuit extending from said dynamo through said sparking device, a battery, a second circuit extending from said battery through the sparking device, said sparking device being arranged in a part of said

circuit common to both, a main overthrow-switch arranged to about the circuit through said battery or dynamo alternatively, a second switch device moving with said main switch device and arranged to control a magnet-circuit in about relation to the dynamo-circuit, an electromagnet in said magnet-circuit, said second switch member being arranged to open the magnet-circuit when the main switch closes the dynamo-circuit through the sparking device, and vice versa, and means operable by said magnet for automatically throwing the main switch into position to close the dynamo-circuit through the sparking device.

4. In an electric ignition system, the combination with a motor and sparking device operated thereby, of a dynamo driven from said motor, an electric circuit extending from said dynamo through said sparking device, a battery, a second circuit extending from said battery through the sparking device, said sparking device being arranged in a part of said circuit common to both, a main overthrow-switch arranged to about the circuit through said battery or dynamo alternatively, a second switch device moving with said main switch device and arranged to control a magnet-circuit in about relation to the dynamo-circuit, an electromagnet in said magnet-circuit, said second switch member being arranged to open the magnet-circuit when the main switch closes the dynamo-circuit through the sparking device, and vice versa, and means operable by said magnet for automatically throwing the main switch into position to close the dynamo-circuit through the sparking device.

5. In an electric ignition system, the combination with a motor and sparking device operated thereby, of a dynamo driven from said motor, a two-point switch having a throw-over switch member and a spring acting upon said switch to normally shift it into engagement with one of said points, a conductor extending from one side of said dynamo to that point of the switch with which said switch member is normally engaged, a second conductor leading from the opposite side of the dynamo to one of the sparking contact devices, a common return-conductor extending from the other sparking contact device to said shiftable switch member, a sparking-coil included in said common conductor, a battery, a conductor extending from said battery to the opposite or normally open point of the two-point switch, a conductor leading from the opposite side of said battery to one of the sparking contacts, an electromagnet-circuit arranged in about relation to the dynamo-circuit, an electromagnet interposed in said circuit provided with a spring-pressed armature yieldably held in open position, a second switch member connected and moving with, but insulated from said main shiftable switch member, and forming a part of said magnet-circuit, said second switch member being adapted for engagement with the armature when the latter is in open position to hold the main switch member in position to close the circuit through the battery against the tension of said spring, substantially as described.

6. In an electric ignition system, the combination with a motor and sparking device, of a dynamo and dynamo-circuit, said dynamo being driven from the motor, a battery and battery-circuit and an electromagnet and magnet-circuit in about relation to the dynamo-circuit, and a switch mechanism operated and controlled by said electromagnet and operating to simultaneously open the battery and magnet circuits, and to close the dynamo-circuit when actuated by the magnet.

696,886. MANUFACTURE OF GOLF-BALLS. BRASER KEMPWELL, Boston, Mass., assignor to the Kempwell Manufacturing Company, a Corporation of New Jersey. Filed Nov. 22, 1901. Serial No. 51,555. (No model.)

Claim.—1. A process in the manufacture of playing-balls, consisting in forming a core, applying a plastic or fluid coating to the core, and permanently compressing said coating upon the core.

2. A process in making golf-balls, consisting in forming a yielding core, applying a plastic or fluid coating to the core, drying said coating, heating and simultaneously subjecting the same to compression to an extent sufficient to compress said core, and maintaining the compression until the shell cools and hardens.

3. A process in making playing-balls, consisting in coating with plastic material a core formed of at least partially of gutta-percha, compressing said coating to an extent to compress said core, and hardening said coating when so compressed.

4. A process in making playing-balls, consisting in coating a yield-

ing core with cellulosic solution, and effecting a hardening and compression of said coating so as to form a shell upon the core.

5. A process in making playing-balls, consisting in coating a core with plastic cellulosic, then drying said coating, and then subjecting the coating to heat and compression.

6. A process in making playing-balls, consisting in coating a core of gutta-percha with cellulosic compound, drying said coating, and subjecting the same to heat and compression to an extent to compress said core.

7. A process in making playing-balls, consisting in applying successive layers of plastic material upon a relatively soft yielding core and then hardening and welding together said layers to form a permanent substantial shell harder than said core.

8. A process in making playing-balls, consisting in applying successive layers of plastic cellulosic upon a yielding core, subjecting said layers to simultaneous compression and heat, and maintaining the compression until the cellulosic hardens.

9. A process in making playing-balls, consisting in applying successive layers of plastic or fluid material upon a soft core, coating said layers to dry, and then subjecting them to heat and efficient compression to reduce the bulk of said core, and maintaining the compression until said plastic material hardens into a permanent shell.

10. A process in making playing-balls, consisting in applying to a yielding core a plurality of layers one after another of fluid or plastic material, drying one layer before another is applied, subjecting the whole to heat and compression to an extent to compress said core and also to cause said layers to weld, and maintaining the compression until the shell hardens.

11. A process in making playing-balls, consisting in applying to a core, consisting at least partially of gutta-percha, a plurality of layers, one after another, of plastic material; drying or partially drying one layer before another is applied; subjecting the whole to heat so as to render said layers plastic and also to compression so as to cause said layers to weld; and maintaining the compression until the shell hardens.

12. A process in making playing-balls, consisting in applying to a yielding core a succession of layers of cellulosic solution, causing one layer to dry before applying the next, subjecting the whole to the action of heat and compression, and maintaining the compression until the cellulosic cools and hardens.

13. A process in making playing-balls, consisting in applying to a core of gutta-percha a succession of layers of cellulosic solution, causing one layer to dry before the next is applied, and then subjecting the whole to the action of heat and compression.

14. The process of making playing-balls, consisting in producing a center piece or filling of gutta-percha, said center piece being somewhat too bulky for the capacity of the finished shell, applying thereto a thick solution of cellulosic in a substantially even layer of one one-hundredth of an inch, more or less, in thickness, allowing the coating to dry to such an extent that it can be handled safely, applying a second coating of like material and allowing it to dry or harden, applying a third coating of like material and if desired one or more additional layers, allowing the third and other coating or coatings to dry or harden, then making an overcoat ball, subjecting the ball to heat and simultaneous compression in dies, and subsequently allowing the ball to cool in the dies; said coatings or layers being welded into an integral shell, which is then condensed, toughened and stiffened, and the core being placed under a compression by the shell.

15. A process in making playing-balls, consisting in forming upon a yielding core a multiple-ply shell of plastic material, then heating said shell to render it plastic throughout, then compressing said shell while heated so as to weld the plies together into an integral shell upon said core, and maintaining the compression until the shell hardens by cooling.

696,887. GOLF-BALL. BRASER KEMPWELL, Boston, Mass., assignor to the Kempwell Manufacturing Company, a Corporation of New Jersey. Filed Nov. 22, 1901. Serial No. 51,556. (No model.)

Claim.—1. A playing-ball comprising an elastic filling, and a hard, springy, substantial cushion shell formed from plastic material and compressed upon said filling and powerfully gripping the latter.

2. A playing-ball comprising a relatively soft elastic filling and a compressed cushion substantial cellulosic shell.

3. A playing-ball comprising a filling held under compression by a relatively hard, springy, substantial, seamless shell.
4. A playing-ball comprising a soft filling held under compression by a seamless, substantial cellular shell.
5. A playing-ball having a filling consisting at least partially of gutta-percha, and a substantial seamless shell formed at least partially of plastic material and compressed upon said filling, and powerfully gripping the latter.
6. A playing-ball comprising an internal mass of gutta-percha and a compressed seamless cellular shell thereon holding said gutta-percha under compression.
7. A playing-ball comprising an internal mass of gutta-percha and a seamless cellular shell, said gutta-percha being held under compression by said shell.
8. A playing-ball comprising an elastic filling and a relatively thin, hard, springy shell consisting of a plurality of seamless layers and holding said filling under compression.
9. A playing-ball comprising an elastic filling and a relatively thin, hard, compressed, springy shell consisting of a plurality of layers welded or fused together and holding said filling under compression.
10. A playing-ball comprising an elastic filling and a relatively thin, springy shell consisting of a plurality of seamless layers welded or fused together, said filling being softer than said shell.
11. A playing-ball comprising a relatively soft compressed elastic filling and a relatively thin, hard, springy shell consisting of a plurality of layers formed from plastic material, said filling being held under compression by said shell.
12. A playing-ball comprising a relatively soft, springy nucleus over which is compressed a seamless cellular shell.
13. A playing-ball consisting of a relatively soft nucleus over which is compressed a shell consisting of a plurality of seamless layers, each layer consisting at least partially of cellular.
14. A playing-ball having an internal mass of gutta-percha and a relatively thin, seamless cellular shell compressed upon said mass and holding the latter under compression.
15. A playing-ball having an internal mass of gutta-percha and a relatively thin shell consisting of several layers of cellular compressed upon said mass and holding the latter under compression.
16. A playing-ball having an internal mass of yielding material and a relatively thin shell consisting of several seamless layers of cellular compressed and welded or joined together and holding said internal mass under compression.
17. A playing-ball comprising a springy nucleus and a plurality of shell layers formed of plastic material and powerfully gripping said nucleus.
18. A playing-ball comprising a springy nucleus and a plurality of shell layers formed of plastic material and powerfully gripping said nucleus, each of said layers consisting at least partially of cellular.

696,888. PROCESS OF MAKING GOLF-BALLS. BRASER KEMPSTALL, Boston, Mass., assignor to the Kempshall Manufacturing Company, a Corporation of New Jersey. Original application filed Nov. 8, 1901, Serial No. 81,598. Divided and this application filed Dec. 12, 1901. Serial No. 95,068. (No model.)

- Claim.—1. A process in producing playing-balls, consisting in compressing shell-segments over a filling previously prepared with a tensioned elastic compression-jacket.
2. A process in producing playing-balls, consisting of inserting within shell-segments an elastic mass having a compression-jacket under tension, the jacketed mass encasing in bulk the capacity of the finished shell, forcing the segments together, causing their contracting portions to adhere, and compressing the shell in final form.
3. A process in producing playing-balls, consisting in inserting within shell-segments an elastic mass having a compression-jacket under tension, the jacketed mass encasing in bulk the capacity of the finished shell, heating the segments, and forcing them together.
4. A process in producing playing-balls, consisting in developing an

- elastic mass with elastic fabric under tension, inserting the same within shell-segments, and forcing the segments together.
5. A process in making playing-balls, consisting in winding elastic bolting around a nucleus of elastic material, making a shell in segments which approximate their final form, and compressing the segments to final form upon the prepared nucleus.
6. A process in making playing-balls, consisting of winding curved layers of elastic bolting around a filling of rubber, making spherical cellular segments, pressing the segments together over the prepared filling so as to compress the same, and uniting the edges of the segments.
7. A process in making playing-balls, consisting of winding elastic bolting under tension around a filling of rubber, treating the bolting with cement, making spherical cellular segments, subjecting them to heat, pressing them together over the prepared filling so as to compress the same, and uniting the edges of the segments.
8. A process in making playing-balls, consisting of making a filling of rubber, providing the same with a retaining-jacket, making hemispherical cellular segments, and compressing the segments over the prepared filling.
9. A method in producing cores for playing-balls, consisting of winding elastic bolting under tension upon an elastic nucleus.
10. A method in producing cores for playing-balls, consisting in winding rubber thread to form a nucleus, and overwinding said nucleus with elastic bolting under tension.
11. A process in producing playing-balls, consisting of winding rubber thread to form a nucleus, and compressing cellular segments over said nucleus.
12. A process in producing playing-balls, consisting of compressing cellular segments over a nucleus of soft rubber and causing the edges to unite or weld.
13. A process in producing playing-balls, consisting of winding elastic bolting upon a nucleus of rubber, and compressing cellular shell-segments thereover.
14. A process in producing playing-balls, consisting of winding rubber thread into the form of a ball, winding elastic bolting under tension upon said ball, and compressing cellular shell-segments thereover.
15. A process in producing playing-balls, consisting of winding rubber thread into the form of a ball, jacketing said ball with fabric or fibrous material and compressing cellular shell-segments thereover.
16. A process in producing playing-balls, consisting of winding rubber thread into the form of a ball, jacketing said ball, treating the jacket with an adherent material, and compressing cellular segments thereover.
17. A process in producing playing-balls, consisting of winding rubber thread into the form of a ball, winding elastic bolting thereover to form a jacket, treating the jacket with adherent material, and compressing cellular segments thereover.

696,889. GOLF-BALL. BRASER KEMPSTALL, Boston, Mass., assignor to the Kempshall Manufacturing Company, a Corporation of New Jersey. Filed Dec. 12, 1901. Serial No. 95,069. (No model.)

- Claim.—1. A playing-ball comprising a springy body formed from plastic material and a nucleus of springy material held under compression at the center of said body, the diameter of said nucleus being less than half the diameter of said body.
2. A playing-ball comprising a gutta-percha sphere and a round soft-rubber core, at the center of said gutta-percha sphere and held under compression thereby; the diameter of said rubber core being a little less than half that of said gutta-percha sphere.
3. A playing-ball, consisting of a body built up from previously-formed gutta-percha spherical sections, said sections being joined edge to edge, and a filling of soft rubber held under compression within said body, the diameter of said soft-rubber filling being less than half that of said gutta-percha body.
4. A playing-ball comprising a body built up of previously-shaped and highly-compressed hemispherical sections of well-seasoned gutta-percha, and a spherical filling of highly-tensioned solid soft rubber held under compression within said body; the relative diameters of said filling and said body being substantially as three-fourths to one and three-fourths.
5. A playing-ball comprising a pellet of soft rubber and compressed

- spherical sections of gutta-percha welded thereon at their edges, the diameter of said pellet being less than half the diameter of the gutta-percha sphere.
6. A playing-ball comprising a sphere of highly-compressed gutta-percha having at its center a pellet of soft rubber, the diameter of said pellet being less than half the diameter of said gutta-percha sphere.
7. A playing-ball comprising a compressed springy body formed from plastic material, and a nucleus of softer elastic material held under compression at the center of said body, the diameter of said nucleus being not more than half the diameter of said body.

696,890. GOLF-BALL. BRASER KEMPSTALL, Boston, Mass., assignor to the Kempshall Manufacturing Company, a Corporation of New Jersey. Filed Jan. 4, 1902. Serial No. 95,419. (No model.)

- Claim.—1. In a playing-ball, a shell of plastic material made up of layers, one of said layers being formed of joined spherical segments, and another of said layers reinforcing the joint, and a yielding filling held under compression by said shell.
2. In a playing-ball, a shell formed largely or wholly of plastic material and comprising a plurality of layers, one of said layers being in the form of joined or welded hemispherical segments, and another of said layers reinforcing the weld, and a yielding filling held under compression by said shell.
3. In a playing-ball, a shell formed largely or wholly of plastic material and comprising two layers, each consisting of joined spherical segments, the joint or seam in one layer running crosswise with the joint or seam in the other layer, and a yielding filling held under compression by said shell.
4. In a playing-ball, a shell comprising an inner and outer layer, each consisting of a plurality of welded segments, and each of said layers reinforcing the weld of the other thereof.
5. In a playing-ball, the combination with a core of a plastic shell comprising at least one layer made up of joined segments and reinforced at the joint by another layer; said shell holding said core under compression.
6. In a playing-ball, the combination of a yielding core and a cellular shell holding said core under compression; said shell comprising inner and outer layers, each of said layers consisting of segments welded together, and the weld in one of said layers running crosswise of the weld in the other thereof.
7. In a playing-ball, the combination with a yielding core, of a shell consisting wholly or partly of cellular and holding said core under compression; said shell consisting of layers, at least one whereof is in the form of segments welded together, and another of said layers reinforcing the weld; said layers being also compressed and welded together likewise.
8. A playing-ball comprising a core consisting wholly or largely of gutta-percha, and a shell consisting wholly or largely of cellular and made up of outer and inner layers, each layer consisting of hemispherical segments welded together, the welds running crosswise of each other; and said layers being solidified and welded together likewise so as to form a concrete shell, which holds said core in a state of compression.
9. In a playing-ball, a shell made up of layers, at least one of said layers consisting of cellular one of said layers being formed of joined spherical segments, and another of said layers reinforcing the joint; and a yielding core held under compression by said shell.
10. In a playing-ball, a shell comprising two layers, at least one of said layers consisting of cellular each consisting of joined spherical segments, the joint or seam in one layer running crosswise with the joint or seam in the other layer; and a yielding core held under compression by said shell.
- 696,891. GOLF-BALL. BRASER KEMPSTALL, Boston, Mass., assignor to the Kempshall Manufacturing Company, a Corporation of New Jersey. Filed Jan. 4, 1902. Serial No. 95,421. (No model.)
- Claim.—1. In a playing-ball, a shell comprising at least three plies, the outer ply being formed of hard, springy, wear-resisting plastic material, an intermediate ply being of fabric, and an inner ply being of hard, springy material.
2. In a playing-ball, a thin shell comprising an outer ply of cellular

a ply of fabric near the outer surface of the ball, and an inner ply of hard, springy material; in combination with a yielding backing for said shell.

3. In a playing-ball, a shell consisting of hard, springy material having separate plies of fabric incorporated therein.
4. A playing-ball comprising a shell having a plurality of thin plies or plates of cellular and a ply or layer of tough material between said cellular plies.
5. In a playing-ball, a shell comprising woven fabric fixed upon both its inner and outer sides with cellular.
6. In a playing-ball, a shell comprising a plurality of plies of fabric alternating with plies of cellular.
7. In a playing-ball, a shell comprising outer and inner plies of cellular, intervening plies of fabric, and cellular between the plies of fabric.
8. In a playing-ball, a shell comprising outer and inner plies of cellular and a plurality of intervening plies of woven fabric.
9. In a playing-ball, a shell consisting of a thin outer ply of well-cured cellular backed by cloth and an inner thin ply of well-cured cellular also backed by cloth; said plies and said cloth being closely compacted.
10. In a playing-ball, a shell consisting of a thin outer ply of well-cured cellular backed by cloth, a thin inner layer of cellular; and an intervening incompletely-cured layer of cellular; said layers and cloth being closely compacted.
11. In a playing-ball, a cellular shell provided with a layer of tough material; the cellular providing an outer and inner facing for said tough material and being closely compacted therewith.
12. In a playing-ball, a shell consisting of welded segments of hard, springy material reinforced by tough material, the latter being in the form of a ply placed between outer and inner plies of said hard, springy material, and all of said plies being closely compacted.
13. In a playing-ball, a shell comprising outer and inner layers, each of said layers consisting of hard, springy material reinforced by tough material, and being formed of segments, the inner layer breaking joints with the outer layer, thereby to prevent tearing of the shell at either joint.
14. In a playing-ball, the combination of an outer and an inner shell layer, each of said layers consisting of hemispherical segments of cloth fixed with cellular and joined at their edges, and the joint of one of said layers crossing the joint of the other of said layers.
15. In a playing-ball, the combination of an outer and an inner shell layer, the inner layer being joined or welded, and the other layer closing or covering the joint or weld of the inner layer so as to form a reinforcement therefor; at least one of said layers being lined with fabric.
16. A playing-ball consisting of a yielding core and a shell holding said core under compression; said shell comprising alternate plies of cellular and fabric closely compacted; and said plies being at least three in number.
17. A playing-ball consisting of a solid sphere of yielding material or materials, and a shell holding said core under compression; said shell comprising closely-compacted plies of cloth alternating with one or more layers of hard, wear-resisting material.
18. A playing-ball consisting of a solid yielding core held under compression by a shell consisting of layers each composed of a ply of fabric fixed with hard, wear-resisting material; such composite layers being formed of segments welded or joined together at their edges.
19. A playing-ball consisting of a yielding core held under compression by a closely-compacted shell consisting of a plurality of layers, at least one of said layers consisting of spherical segments of combined fabric and cellular.
20. A playing-ball consisting of a yielding core held under compression by a closely-compacted thin shell consisting of a plurality of layers, each layer consisting of a plurality of joined fabric and cellular segments, and the joint or seam in one layer crossing the joint or seam in another layer.
21. A playing-ball consisting of a yielding core held under compression by a relatively thin closely-compacted shell consisting of a plurality of layers, each layer consisting of joined hemispherical fabric and cellular segments, the joint or seam in one layer extending crosswise of the joint or seam in the other layer.
22. In a playing-ball, the combination with a core of a shell or covering consisting of segments welded or joined at their edges, each segment comprising a ply of fabric and a layer of hard, wear-resisting, plastic springy material closely compacted with said fabric.

23. In a playing-ball, the combination of a hemispherical cover, segments joined at their edges, each segment comprising a layer of woven fabric and a layer of celluloid; and a reinforcing-cover for the joint or seam.

24. In a playing-ball, the combination of a core; spherical segments, each comprising a layer of woven fabric and a layer of celluloid, said segments meeting the core and being welded at their edges; and a fabric reinforcement for the void.

25. In a playing-ball, the combination of a relatively massive solid core, and a relatively thin shell consisting of an inner layer, an outer layer, and an intervening layer; said inner and outer layers consisting of cloth having celluloid embedded therein, and each being formed of segments welded at their edges, the voids meeting; said intervening layer being also of celluloid and firmly uniting said inner and outer layers; and said shell being compressed upon said core and holding the latter under compression.

26. In a playing-ball, the combination with a yielding core of a shell consisting of fabric and hard, wear-resisting material in alternate layers; said layers being welded into the form of a concrete substance and holding said core under compression.

27. In a playing-ball, the combination of celluloid segments or plates joined at their edges, to form a cover, and a fabric reinforcement covering the joints.

28. A playing-ball having a casing comprising an outer substantial layer of celluloid lined with fabric, said layer being formed in spherical segments which are welded together at their edges.

29. A playing-ball having a filling and a shell holding said filling under compression; said shell including an outer substantial layer of celluloid lined with fabric, said layer being formed in hemispherical segments which are welded together at their edges.

30. A playing-ball comprising a yielding filling and a shell, said shell being compounded of fabric and celluloid.

31. A playing-ball comprising a spherical body which consists of layers of fabric and layers of celluloid.

32. A playing-ball comprising a yielding filling and a shell, said shell being compounded of a plurality of layers of celluloid and at least one layer of woven fabric.

33. A playing-ball comprising a yielding filling and a shell holding the filling under compression, said shell being formed from hemispherical segments welded together at their edges, and the shell including a plurality of layers of celluloid and at least one layer of woven fabric.

34. A playing-ball comprising a yielding filling and a shell, said shell being compounded of a plurality of layers of fabric and at least one layer of celluloid.

35. A ball formed in united hemispherical cups formed from celluloid in which fabric is embedded.

36. A ball formed in united spherical segments formed from celluloid which is united to woven fabric.

37. A playing-ball having a yielding filling and a shell consisting of fabric and celluloid; said shell holding said filling under compression.

38. A playing-ball having a yielding filling and a substantial shell consisting of celluloid and fabric in layers; said shell being formed in spherical segments which are welded together at their edges upon said filling; and said shell holding said filling under compression.

696,892. GOLF-BALL. BRADEN KNUFVALL, Boston, Mass., assignor to the Kumpshall Manufacturing Company, a Corporation of New Jersey. Filed Jan. 20, 1900. Serial No. 90,442. (No model.)

Claim.—1. A playing-ball comprising a spherical rubber envelop distended by a filling of gutta-percha, and a shell built up of gutta-percha and celluloid and compressed upon said envelop.

2. A playing-ball comprising a relatively large spherical core of gutta-percha, a solid soft-rubber spherical envelop thereon, a gutta-percha shell upon said envelop, and a celluloid covering upon said shell.

3. A playing-ball comprising a spherical gutta-percha core, a soft-rubber envelop thereon, a relatively thick gutta-percha shell upon said envelop, and a celluloid covering upon said shell; said celluloid covering being materially thicker than said gutta-percha shell.

4. A playing-ball comprising a spherical gutta-percha core, a solid

soft-rubber spherical envelop thereon, a gutta-percha shell upon said envelop, and a celluloid covering upon said shell; said celluloid and gutta-percha shell being compressed upon said envelop.

5. A playing-ball comprising a spherical gutta-percha core, a solid soft-rubber envelop thereon, a gutta-percha shell upon said envelop, and a celluloid covering upon said shell; said celluloid shell being formed in segments welded and compressed upon the filled gutta-percha shell.

6. A playing-ball comprising a gutta-percha spherical core, a soft-rubber envelop thereon, a gutta-percha shell upon said envelop, and a celluloid covering upon said shell; said gutta-percha shell being formed in segments welded and compressed upon said soft-rubber envelop.

7. A playing-ball comprising a gutta-percha core, a soft-rubber envelop, a gutta-percha shell upon said envelop, and a celluloid covering upon said shell; said gutta-percha and celluloid shell components being made in sections all of which are welded and compressed upon said soft-rubber envelop.

8. A playing-ball comprising a gutta-percha core, a soft-rubber envelop thereon, a gutta-percha shell upon said envelop, and a celluloid covering upon said shell; said gutta-percha and celluloid shell components being made in sections which are welded and compressed upon said filling, and the void or joint in the celluloid covering meeting the void or joint in the gutta-percha shell.

9. A playing-ball comprising a core which is inclusive of a spherical body of india-rubber, and a shell compounded of gutta-percha and celluloid and compressed upon said core.

10. A playing-ball comprising a relatively large sphere of gutta-percha, a shell compounded of gutta-percha and celluloid, and an intervening layer of soft, springy material; said shell being compressed upon said intervening layer and core.

11. A playing-ball comprising a yielding filling and a shell compounded of welded segments of gutta-percha and welded segments of celluloid; the voids or joints meeting.

12. A playing-ball comprising a yielding filling and a shell compounded of welded segments of gutta-percha and welded segments of celluloid; the voids or joints meeting.

13. A playing-ball comprising a hard core, a soft and highly-elastic sphere thereon, a harder and less elastic sphere upon said sphere, and a still harder and still less elastic casing upon the last-mentioned sphere.

14. A playing-ball comprising a relatively hard outer shell, an inner gutta-percha shell, and a spherical filling within said gutta-percha shell, at least the exterior of said filling consisting of soft rubber.

15. A playing-ball comprising a hard core, a soft and highly-elastic sphere expanded thereon, a harder and less elastic sphere upon said sphere, and a still harder and still less elastic casing upon the last-mentioned sphere.

16. A playing-ball comprising a relatively hard outer shell, an inner gutta-percha shell, a rubber sphere within said gutta-percha shell, and a hard core upon which said rubber sphere is expanded.

17. A playing-ball comprising a hard core formed in a highly-yielding sphere, said sphere being in a state of expansion upon said core, a more resilient shell layer upon said sphere, and a still more resilient outer layer upon said shell layer.

696,898. GOLF-BALL. BRADEN KNUFVALL, Boston, Mass., assignor to the Kumpshall Manufacturing Company, a Corporation of New Jersey. Filed Jan. 21, 1900. Serial No. 91,575. (No model.)

Claim.—1. A playing-ball comprising a spherical rubber envelop distended by a filling of gutta-percha, and a shell built up of gutta-percha and celluloid and compressed upon said envelop, the celluloid portion of the shell being common.

2. A playing-ball comprising a spherical core of gutta-percha, a solid soft-rubber spherical envelop thereon, a gutta-percha shell upon said envelop, and a plurality of elastic layers of celluloid meeting said shell.

3. A playing-ball comprising a spherical gutta-percha core, a soft-rubber envelop thereon, a relatively thick gutta-percha shell upon said envelop, and a celluloid covering upon said shell; said celluloid covering being materially thicker than said gutta-percha shell, and comprising a plurality of elastic layers fused or welded together.

4. A playing-ball comprising a spherical gutta-percha core, a solid soft-rubber spherical envelop thereon, a gutta-percha shell upon said en-

volep, and a seamless celluloid covering upon said shell; said celluloid and gutta-percha shell being compressed upon said envelop.

5. A playing-ball comprising a gutta-percha spherical core, a soft-rubber envelop thereon, a gutta-percha shell upon said envelop, and a multiple-ply thin celluloid covering compressed upon said shell; said gutta-percha shell being formed in segments welded and compressed upon said filling.

6. A playing-ball comprising a gutta-percha core, a soft-rubber envelop, a gutta-percha shell upon said envelop, and a celluloid covering upon said shell; said gutta-percha shell being made in sections or portions which are welded and compressed upon said filling, and said celluloid comprising a plurality of welded coatings compressed upon said shell.

7. A playing-ball comprising a gutta-percha core, a soft-rubber envelop thereon, a gutta-percha shell upon said envelop, and a thin celluloid covering upon said shell; said gutta-percha shell being made in sections which are welded and compressed upon said filling, and the celluloid covering comprising a plurality of seamless layers welded together and compressed upon said shell.

8. A playing-ball comprising a core which is inclusive of a spherical body of india-rubber, a shell of gutta-percha compressed upon said core and a seamless celluloid casing compressed upon said shell.

9. A playing-ball comprising a relatively large sphere of gutta-percha, a shell of gutta-percha; an intervening layer of soft, springy material; said shell being compressed upon said intervening layer and core; and a thin seamless casing of celluloid compressed upon said shell.

10. A playing-ball comprising a yielding filling, a thick gutta-percha shell compressed thereon; and a thin seamless celluloid casing compressed upon said shell.

11. A playing-ball having an internal mass of rubber and gutta-percha and a seamless casing or shell of hard, wear-resisting material.

12. A playing-ball having an internal mass of soft rubber and gutta-percha and a seamless celluloid casing or shell.

13. A playing-ball having an internal mass of soft rubber and gutta-percha and a seamless celluloid casing compressed thereon.

14. A playing-ball having an internal mass of gutta-percha and soft rubber and a relatively thin seamless celluloid shell compressed to the open end mass so as to hold the latter under compression.

15. A playing-ball having an internal mass of gutta-percha and rubber and a relatively thin shell consisting of several layers of celluloid compressed upon said mass so as to hold the latter under compression.

696,894. GOLF-BALL. BRADEN KNUFVALL, Boston, Mass., assignor to the Kumpshall Manufacturing Company, a Corporation of New Jersey. Filed Feb. 14, 1900. Serial No. 94,596. (No model.)

Claim.—1. A playing-ball comprising a casing made in sections, said casing consisting of plastic material lined with fabric, each section having inward-pointing portions which are nested in the ball.

2. A playing-ball comprising a casing made in sections, said casing consisting of plastic material lined with fabric, each section having tongues which are turned into the ball, and the tongues upon one section lying against the tongues upon the other section, and all of said tongues lying in the joint or joints of the ball.

3. A playing-ball comprising a casing of celluloid and fabric, said casing having inward-pointing portions that lay the same to the body of the ball.

4. A playing-ball having a casing consisting of celluloid and fabric formed in segments and having portions which are turned in between the jointed body portions or segments of the ball.

5. A playing-ball comprising hemispherical cover-segments consisting of fabric-lined material each having inwardly-turned tongues, the tongues of one segment opposing those of the other segment, whereby said segments are locked or lapped upon the ball.

6. A playing-ball comprising joined hemispherical segments formed in wear-resisting material; portions of the casing material being turned in between said segments.

7. A playing-ball comprising joined hemispherical segments covered with hemispherical segments of wear-resisting material; each of the cover-segments having tongues which are turned in between the first-mentioned segments.

8. A playing-ball comprising joined or welded hemispheres of gutta-percha covered by hemispheres of celluloid; each of the celluloid hemispheres having tongues which are turned in between said hemispheres of gutta-percha.

9. A playing-ball comprising a core, and hemispheres of gutta-percha joined or welded thereon, and hemispheres compounded of fabric and celluloid meeting said gutta-percha; each of the meeting hemispheres having tongues which are turned in between the hemispheres of gutta-percha.

10. A playing-ball comprising a core; and hemispheres of gutta-percha joined or welded thereon, and hemispheres compounded of fabric and celluloid meeting said gutta-percha; each of the meeting hemispheres having tongues which are turned in between the hemispheres of gutta-percha, and the tongues upon one of said meeting hemispheres being opposed to those upon the other thereof.

11. A playing-ball comprising a sphere of soft rubber; hemispheres of gutta-percha welded or joined upon said sphere; and a covering consisting of hemispheres of fabric and celluloid covered upon said gutta-percha; each of said covering hemispheres having tongues turned in between the hemispheres of gutta-percha.

12. A playing-ball comprising a sphere of gutta-percha; a spherical soft-rubber envelop thereon; an outer sphere of gutta-percha upon said envelop; and a covering compounded of celluloid and fabric, portions whereof are nested or lapped in said outer gutta-percha sphere.

13. A playing-ball comprising a sphere of gutta-percha; a spherical soft-rubber envelop thereon; hemispheres of gutta-percha welded or joined upon said envelop; and a cover consisting of hemispheres of compounded fabric and celluloid meeting said gutta-percha; each of the covering hemispheres having tongues turned in between said hemispheres of gutta-percha.

14. A solid playing-ball having a celluloid cover made in joined segments, each segment having devices or portions which extend into the body of the ball, and said cover being compressed upon the ball, so as to hold the interior of the ball permanently under compression.

15. A playing-ball comprising a celluloid cover made in segments, each segment having tongues which are turned into the ball between the joints thereof, and said cover being compressed upon the ball.

16. A playing-ball comprising a celluloid cover made in segments, each segment having tongues which are turned into the ball between the joints thereof, the tongues upon one segment being connected or attached to the tongues upon the other segment, and said cover being compressed upon the ball.

17. A playing-ball comprising a yielding interior portion, and a cover of celluloid which is compressed upon the ball and holds the body thereof under permanent compression; said cover having inwardly-extended portions or parts which lay it to the body of the ball.

18. A playing-ball comprising a joined interior portion, and welded or joined hemispherical cover-segments compounded of fabric and celluloid; each of said segments having tongues turned in between the joints of the interior portion, and said cover being compressed upon the ball.

19. A playing-ball comprising joined or welded spherical segments covered with a material compounded of at least one layer of treated fabric and at least one layer of celluloid, said material being connected and the celluloid permeating the fabric; and said cover being compressed, and lapped upon the ball.

20. A playing-ball comprising joined or welded spherical segments covered with a material compounded of at least one layer of treated fabric and at least one layer of celluloid, said material being connected and the celluloid permeating the fabric; portions of said cover being turned in between said segments; and said cover being compressed, and lapped upon the ball.

21. A playing-ball comprising a cover of wear-resisting material compounded of at least one layer of fabric impregnated and fused upon both sides with celluloid; said cover being formed in segments and having tongues which are turned in between segments of which an inner portion of the ball is formed.

22. A playing-ball comprising a cover of wear-resisting material compounded of at least one layer of fabric impregnated and fused upon both sides with celluloid; said cover being lapped and compressed upon the ball.

23. A playing-ball comprising joined or welded hemispheres of gutta-percha formed by hemispheres of celluloid; each of the celluloid hemispheres having tongues which are turned in between the hemispheres of gutta-percha, and said segments and said casing being compressed upon the ball.

24. A playing-ball comprising a core and joined or welded hemi-

spheres of gutta-percha thereon and covered by hemispheres compounded of fabric and celluloid; each of the covering-hemispheres having tongues which are turned in between the hemispheres of gutta-percha, and the tongues upon one of said covering-hemispheres being opposed to those upon the other thereof; said gutta-percha and celluloid being solidified and holding said core under compression.

25. A playing-ball comprising a sphere of soft rubber; hemispheres of gutta-percha welded or joined upon said sphere; and a cover consisting of hemispheres of fabric and celluloid secured upon said gutta-percha; each of the covering-hemispheres having tongues turned in between the hemispheres of gutta-percha, and said gutta-percha and celluloid holding said core under compression.

26. A playing-ball comprising a sphere of gutta-percha; a spherical soft-rubber envelop thereon; an outer sphere of gutta-percha upon said envelop; and a covering compounded of celluloid and fabric, portions whereof are rooted or keyed in said outer gutta-percha sphere; said gutta-percha and celluloid holding said core under compression.

27. A playing-ball comprising a sphere of gutta-percha; a spherical soft-rubber envelop thereon; hemispheres of gutta-percha welded or joined upon said sphere; and a covering consisting of hemispheres compounded of fabric and celluloid secured upon said gutta-percha; each of the covering-hemispheres having tongues turned in between the hemispheres of gutta-percha, and said gutta-percha and celluloid holding said core under compression.

28. In a playing-ball, the combination of a filling, a cover made in segments, each of said segments having interned border portions and projections which are clenched between portions of the filling or interior mass of the ball.

29. In a playing-ball, a celluloid cover made in hemispherical segments, each segment having a substantially continuous interned border or brim, and projections.

30. In a playing-ball, a celluloid cover made in hemispherical segments, each segment having a substantially continuous interned border or brim and also a number of projections or tongues extending inwardly beyond said brim.

31. In a playing-ball, the combination with joined or welded segments of gutta-percha of segments compounded of celluloid and fabric covering the gutta-percha, said celluloid and fabric segments having inwardly-turned borders or brims and tongues extending between the segments of gutta-percha.

32. A playing-ball comprising a thin celluloid cover made in segments, each segment having an interned brim, and projections.

33. A playing-ball comprising a thin celluloid and fabric cover made in hemispherical segments, each segment having an interned brim, and said brims being united and the cover being compressed upon said ball.

34. A playing-ball comprising joined or welded spherical gutta-percha segments covered with a material compounded of at least one layer of treated fabric and at least one layer of celluloid, said material being cemented and the celluloid permeating the fabric; and said cover being compressed, and keyed upon the ball.

35. A playing-ball comprising a sphere of soft rubber, and a shell of gutta-percha thereon, said shell being covered with a material compounded of at least one layer of treated fabric and at least one layer of celluloid, said material being cemented and the celluloid permeating the fabric and said cover being compressed, and keyed upon the ball.

36. A playing-ball comprising a solid core of gutta-percha covered by a sphere of soft rubber, and a shell of gutta-percha thereon, said shell being covered with a material compounded of at least one layer of treated fabric and at least one layer of celluloid, said material being cemented and the celluloid permeating the fabric; and said cover being compressed, and keyed upon the ball.

37. In a playing-ball, the combination with a yielding filling, of a shell comprising an outer layer of celluloid, a layer of fabric, and a layer of gutta-percha.

38. In a playing-ball, the combination with a sphere of gutta-percha of a shell or casing thereon consisting wholly of an outer layer of celluloid and a lining of fabric.

39. In a playing-ball, the combination with a yielding filling, of a layer of gutta-percha thereon, and a casing upon said gutta-percha layer, said casing being thinner than said gutta-percha layer and consisting of celluloid lined with fabric.

40. A playing-ball having a springy filling and provided with a casing consisting of a single ply of celluloid lined with fabric.

41. A playing-ball having a springy filling and provided with a casing consisting of a single ply of celluloid lined with a single ply of fabric.

42. A playing-ball comprising a springy filling and a shell holding said filling under compression; said shell including a single ply of celluloid lined with fabric, and said celluloid forming the casing or periphery of the ball.

43. A playing-ball comprising a yielding filling and a shell holding

said filling under compression and comprising gutta-percha, fabric and celluloid, the celluloid forming the casing of the ball, and the fabric being between the celluloid and the gutta-percha.

44. A playing-ball comprising a yielding filling and a shell; said shell comprising spherical segments of gutta-percha welded together, and also comprising a casing consisting of fabric and celluloid; and said shell holding said filling under compression.

45. A playing-ball comprising a springy filling and a shell consisting of spherical segments welded at their edges and holding said filling under compression; said shell being inclusive of a single ply of celluloid and a single ply of fabric forming a lining for the latter.

696,895. GOLF-BALL. ELIZABETH KEMPSTALL, Boston, Mass., assignor to the Kempshall Manufacturing Company, a Corporation of New Jersey. Filed Feb. 24, 1902. Serial No. 96,151. (No model.)

Claim.—1. In a playing-ball, the combination with a springy core of a shell comprising at least two plies, the outer ply being of hard, springy, wear-resisting material, and the inner ply being of fabric cemented to said core; said shell holding said core under compression.

2. In a playing-ball, a thin shell comprising an outer ply of celluloid, a ply of fabric near the outer surface of the ball, and an inner ply of celluloid interiorly faced with fabric; in combination with a yielding core to which said fabric is cemented.

3. In a playing-ball, a shell consisting of hard, springy material having separate plies of fabric incorporated therein, including an interior facing-ply; and a core to which said facing-ply is cemented.

4. A playing-ball comprising a core, a compacted shell having a plurality of thin plies or plates of celluloid, a ply or layer of tough material between said celluloid plies, and an inner facing of cloth cemented to said core.

5. In a playing-ball, a shell comprising celluloid and woven fabric embedded therein, and a springy core to which said shell is cemented.

6. In a playing-ball, a shell comprising a plurality of plies of fabric alternating with plies of celluloid, and a core consisting partly or wholly of rubber to which said shell is cemented.

7. In a playing-ball, a shell comprising an outer ply of celluloid, an inner ply of fabric, intervening plies of fabric and celluloid, and a core to which said inner ply of fabric is cemented, said core consisting partly or wholly of rubber.

8. In a playing-ball, a compacted shell comprising an outer ply of celluloid, an inner ply of fabric, and a core to which said inner ply is cemented.

9. In a playing-ball, a shell comprising a thin outer ply of celluloid backed by cloth, and an inner thin ply of celluloid interiorly faced with cloth; said plies and said cloth being closely compacted; and a core to which said interior facing is cemented.

10. In a playing-ball, the combination with a springy core of a shell cemented thereto and comprising outer and inner layers, each of said layers consisting of hard, springy material reinforced by tough material, and being formed of segments, the inner layer breaking joints with the outer layer, thereby to prevent bursting of the shell at either joint.

11. In a playing-ball, the combination with a sphere of rubber of an outer and an inner shell layer, each of said layers consisting of hemispherical segments of celluloid interiorly faced with cloth and joined at their edges, the inner layer being cemented to said rubber, and the joint of one of said layers crossing the joint of the other of said layers.

12. In a playing-ball, the combination with a core consisting partly or wholly of rubber of an outer and an inner shell layer, the inner layer being jointed or welded, and the other layer closing or covering the joint or weld of the inner layer so as to form a reinforcement therefor; and said inner layer being cemented to said rubber.

13. A playing-ball consisting of a yielding core and a shell cemented to said core and holding it under compression; said shell comprising alternate plies of celluloid and fabric closely compacted; and said plies being at least three in number.

14. A playing-ball consisting of a solid sphere of yielding material or materials, and a shell holding said core under compression; said shell comprising closely-compacted plies of cloth alternating with one or more layers of hard, wear-resisting material, the inner surface of said shell being of cloth, which is cemented to said core.

15. A playing-ball consisting of a solid yielding core held under compression by a shell consisting of layers each composed of a ply of fabric faced with hard, wear-resisting material; each composite layer being formed of segments welded or joined together at their edges, and being cemented to the core.

16. A playing-ball consisting of a yielding core held under compression by a closely-compacted shell consisting of a plurality of layers, at least the inner one of said layers consisting of spherical segments of celluloid faced upon its inner side with fabric, and cemented to said core.

17. A playing-ball consisting of a yielding core upon which is cemented a closely-compacted thin shell consisting of a plurality of layers, each layer consisting of a plurality of joined celluloid segments, each faced upon its inner side with fabric, and the joint or seam in one layer crossing the joint or seam in another layer.

18. A playing-ball consisting of a yielding core held under compression by a relatively thin closely-compacted shell consisting of a plurality of layers, each layer consisting of joined hemispherical fabric and celluloid segments, the fabric being upon the inner side of each layer, the joint or seam in one layer extending crosswise of the joint or seam in the other layer, and the shell being cemented to the core.

19. In a playing-ball, the combination with a core of a shell or covering comprising segments welded or joined at their edges and cemented to said core; each segment comprising a ply of fabric and a layer of hard, wear-resisting, springy material closely compacted with said fabric.

20. In a playing-ball, the combination of a core of springy material; hemispherical cover-segments joined at their edges and cemented upon said core; each segment comprising an inner layer of woven fabric, as 22, and a layer of celluloid, as 21; and a reinforcing-cover, as 23, 24, for the joint or seam.

21. In a playing ball, the combination of a core; spherical segments, each comprising an inner layer of woven fabric, as 22, and a layer of celluloid, as 21; said segments being welded at their edges and cemented upon the core; and a fabric reinforcement, as 23, for the wall.

22. In a playing-ball, the combination of a relatively massive solid core, and a relatively thin shell consisting of an inner layer, an outer layer, and an intervening layer; said inner and outer layers consisting of cloth having celluloid embedded therein, and each being formed of segments welded at their edges, the walls crossing; said intervening layer being also of celluloid and firmly uniting said outer and inner layers; and said shell being compacted upon and cemented to said core and holding the latter under compression.

23. In a playing-ball, the combination with a yielding core of a shell cemented thereto and consisting of fabric and hard, wear-resisting material in alternate layers; said layers being welded into the form of a concrete substance and holding said core under compression.

24. In a playing-ball, the combination of a springy core; celluloid segments or plates joined at their edges, to form a cover, and cemented upon said core; and a fabric reinforcement covering the joints.

25. In a playing-ball, a shell consisting of at least partially of celluloid and cemented to and compressed upon a springy core, and holding the latter under compression.

26. In a playing-ball, the combination of a core and a shell cemented thereto; said shell consisting of an outer ply of celluloid, then a ply of fabric, then a second ply of celluloid, then a second ply of fabric, then a third ply of celluloid, and then a third ply of fabric.

27. In a playing-ball, the combination with a filling of a shell or casing cemented thereto and consisting of celluloid lined with fabric.

28. In a playing-ball, the combination with a filling of a shell cemented to said filling and holding the latter under compression, said shell consisting of celluloid lined with woven fabric.

29. A ball incased in and cemented to united hemispherical cups formed from celluloid in which fabric is embedded.

30. A ball incased in and cemented to united spherical segments formed from celluloid which is united with woven fabric.

31. A playing-ball having a filling and a shell cemented to said filling and holding the latter under compression; said shell including an outer layer of celluloid lined with fabric, said layer being formed in hemispherical segments which are welded together at their edges.

32. A playing-ball comprising a yielding filling and a shell cemented thereto; said shell being compounded of fabric and celluloid.

33. A playing-ball comprising a yielding filling and a shell cemented to and holding said filling under compression, said shell being formed from hemispherical segments welded together at their edges, and the shell including a plurality of layers of celluloid and at least one layer of woven fabric.

696,896. STOVE-SHELF. EDGAR W. ANTHONY, Brooklyn, Mass., assignor to Smith and Anthony Company, Boston, Mass., a Corporation of Massachusetts. Filed Mar. 15, 1901. Serial No. 21,262. (No model.)

Claim.—1. In a stove or range a shelf, an independent rim or band, two or more bars attached to said rim, means connected to the outer edge of said shelf to support said bars in slidable relation to said shelf, said means being located slightly beyond the outer edge of said shelf forming an opening larger than the cross-section of said bars, and a vertically-projecting stop located near the end of each bar, whereby said rim may be moved away from said shelf and maintained in a horizontal position, and when raised slightly in its extreme outer position may be entirely disconnected from said shelf, as described.

2. In a stove or range a shelf, an independent rim or band, two or more bars connected to said rim, means connected to the outer edge of said shelf to support said bars in slidable relation to said shelf, each of said bars having a lock located at its end nearest said rim to lock said rim against said shelf, and a stop at its outer end to prevent its being withdrawn from said shelf when moved outwardly, as and for the purposes described.

3. The combination in a stove or range of a shelf or plate having a false rim or band cut in from the main rim or band with a movable section of the main rim or band adapted to be moved to and from the false rim or band and when in contact with the false rim or band to be flush with the fixed section of the main rim or band.

4. The combination in a stove or range of a shelf or plate having at its front edge bearings for slide-bars, a movable section of a rim or band attached to the outer ends of the slide-bars, guides upon the under surface of the plate or shelf for governing the movement of the bars, lugs for engaging the ends of the bars when near the end of their inner movement and then hold them from moving downward, the said bars having at their inner ends raised surfaces adapted to ride upon the under surface of the shelf.

5. The combination in a stove or range of a shelf or plate, a movable section of its rim or band, slide-bars to the ends of which said movable section is secured, bearings for the slide-bars and guiding and holding devices upon the under side of the plate or shelf for the slide-bars, the holding devices acting to hold the slide-bars for a portion of their movement only and to then become disengaged from them whereby the bars may be tipped and in their tipped position removed entirely from the shelf or plate.

6. The combination in a stove, of a shelf or plate having a false rim or band cut in from the main rim or band, with a movable section of the main rim or band, one or more connections attaching said movable section of said main rim or band to said false rim or band, and means whereby when said movable section is in contact with said false rim or band it will be locked in place, as and for the purposes described.

7. The combination of a shelf or plate having a false rim cut in from the main rim and a movable section of said main rim adapted to be moved to and from said false rim, and when in contact with said false rim to be flush with the fixed section of said main rim, one or more connections attaching said movable section to said shelf, each of which has a top bearing and a stop at its inner end, an incline and a notch at its outer end, the shelf or plate being raised over its connections to permit a slight upward movement and also having a bearing which coacts with the incline as described.

696,897. THILL-COUPLES. McKENNON F. BAKER and MARTIN A. TOLIER, San Jose, Cal.; said Tolier assignor to said Baker, and I. W. Winans, Plymouth, Cal. Filed Dec. 27, 1899. Serial No. 790,448. (No model.)

Claim.—1. A thill-coupling having a rocking and a stationary member, a loose pin passing through said stationary member and adapted to enter a cavity in said rocking member, said pin being formed with an enlarged head for the purpose of limiting its play, all substantially as shown and for the purposes set forth.

2. In the thill-coupling described, the combination of the clip, the plate receiving the arms of the clip and having its upper side rabbeted at its rear end and also having the concave-convex portion at its forward end forming a seat, the spring having its upper rear end seated in the rabbet

of the clip-plate and receiving one arm of the clip and also having a forwardly-extending arm terminating in a hook, the thill-iron having the rounded end resting in the seat of the clip-plate, and the clevis pivotally connected to said end of the thill-iron and having a contracted lower portion, substantially as described.

3. In a thill-coupling, the combination of a body or plate, a thill-iron bearing therein, a clevis pivotally connected to and depending from the thill-iron and having a lower contracted portion and a spring connected with the body or plate and having an arm engaging the light of the clevis, substantially as described.

696,898. SHALE-ROCK PLOW. HENRY C. BOWLER, Danville, Ill. assignor of one-half to William Butler, Danville, Ill. Filed Feb. 26, 1901. Serial No. 45,582. (No model.)

Claim.—1. A combination plow and crusher comprising a platform having a continuous under crushing-surface adapted to contact with and by the inherent weight of the platform to crush the plowed material, plow-blades secured in and extending beneath the platform and means for vertically adjusting the blades.

2. A combination plow and crusher comprising a platform having a continuous under crushing-surface adapted to contact with and by the inherent weight of the platform to crush the plowed material, and a plurality of vertically-adjustable standards provided with plow blades or points one of the standards being positioned at a distance from the other standards equal to double the space between the latter and forming a guide for the movement of the plow.

3. The combination of the platform A, blade-standards B, E, F, extending through and adjustably secured to the platform, plate B, having draft-attaching means C, secured to the platform, brace-plate U for the plate B, and sheave D on the plate B, substantially as described.

696,899. END-GATE-ROD FASTENER. WILLIAM A. DAY, City Center, Neb. Filed Nov. 18, 1901. Serial No. 82,371. (No model.)

Claim.—1. An end-gate-rod fastener, comprising a rod for engagement with an end-gate and the sides of a wagon-body, a sectional nut forming a permanent fixture of one side of the wagon-body, the threaded end of the rod being engaged by the said sectional nut, and a lever device for the said nut, to open the end-gate thereof and thereby discharge the nut from the threads of the rod, as set forth.

2. An end-gate-rod fastener, comprising a rod for engagement with an end-gate and the sides of a wagon-body, a nut for engaging the threaded end of the rod and formed of pivoted nut sections, and a lever connected with the free ends of the said nut-sections to simultaneously open or close the nut-sections, as set forth.

3. An end-gate-rod fastener, comprising a rod for engagement with an end-gate and the sides of a wagon-body, a nut for engaging the threaded end of the rod, the nut being formed of sections pivoted on the sides of the wagon-body, a lever having a recess at its fulcrum end to engage the free end of one of the nut-sections, and a link connecting the free end of the other nut-section with the fulcrum end of the lever, as set forth.

696,900. FATTY COMPOUND OF IODINE AND SULFUR AND PROCESS OF MAKING SAME. OTTO DUMMER, Eberhard, Germany, assignor to Farbwerke von Eberhard & Co., New York, N. Y., a Corporation of New York. Filed Dec. 21, 1901. Serial No. 96,898. (Specimen.)

Claim.—1. The process for producing new derivatives of fat containing sulfur and iodine, which process consists in at first treating fat with iodine and hydrogen sulfide, secondly purifying the reaction mass and thirdly isolating the new compounds, substantially as hereinbefore described.

2. The process for producing a new derivative of essence-oil containing iodine and sulfur, which process consists in at first treating essence-oil with iodine and hydrogen sulfide, secondly purifying the reaction mass and thirdly isolating the new compound, substantially as hereinbefore described.

3. The herein-described new derivative of fat containing in the molecule iodine and sulfur being more or less colored oily liquids soluble in benzene, ether and ligroin which do not split off iodine when heated on the water-bath and being valuable remedies, substantially as described.

4. The herein-described specific derivative of essence-oil containing iodine and sulfur being a yellowish-brown oil soluble in benzene, ether and ligroin with a yellowish color, iodine and sulfur being so intimately combined therein with the molecule that they cannot be discovered by means of the usual agents, being decomposed when heated over a free flame with disengagement of violet vapors of iodine and representing a valuable remedy, substantially as hereinbefore described.

696,901. CAR-BRAKE. CHARLES R. FAIRCHILD, New York, N. Y. assignor of one-fourth to Edward T. Postelwaite, Philadelphia, Pa. Filed July 2, 1901. Serial No. 66,864. (No model.)

Claim.—1. The combination in a device for operating the brake-gear of a car, of a shaft, a drum thereon, a rope partly wound on the drum, and a pulley over which a loop of said rope extends, with means for operatively connecting the brake-gear of the car to the said shaft, the said loop of rope extending within the reach of an operator substantially as described.

2. The combination of a car, brake-gear thereon, a threaded shaft on the car, a nut on said threaded shaft, the brake-gear being connected to said nut, a drum fixed to the shaft, a pulley on the platform of the car and a rope partially wound on the drum and extending over the pulley on the platform within reach of an operator thereon substantially as described.

3. The combination with a car and the braking mechanism thereof, of a nut and a threaded shaft, the same comprising members of which one is revolvable, a drum fixed to the revolvable member, a connection between the brake-gear and the second member and a rope extending around the drum whereby the device may be operated substantially as described.

4. The combination with a car having brake-gear, of a threaded shaft supported in bearing from said car, a drum keyed to said shaft, a rope wound on said drum for turning the same, a nut constructed to fit the threaded shaft and a casing attached to the said nut and extending around the end of said shaft, said casing being connected to the brake-gear, substantially as described.

5. In a device for operating the brake-gear of a car, the combination of a member fixed to prevent longitudinal motion, and a second member fixed to prevent rotary motion, a drum fixed to the first member, means wound on said drum whereby it may be made to revolve and a connection between the second member and the brake-gear, with means constructed to guide and support said second member as it is moved longitudinally, substantially as described.

6. The combination in a device of the character described, of a frame hung from the bottom of a car, a threaded shaft journaled in one of the members thereof, a threaded nut operative on the shaft and connected to the brake-gear of the car, said nut being guided on said frame, a drum on the shaft and a rope whereby said drum is made to revolve, substantially as described.

7. The combination of a car, brake-gear thereon, a threaded shaft supported from said car, a drum thereon, a threaded nut operative on the shaft, a casing surrounding the shaft and its cooperative parts, and a nut connected to the brake-gear of the car extending through an opening in said casing and connected to said threaded nut, with means wound upon the drum for turning the same, substantially as described.

696,902. BORING-TOOL. JOHN GRAY, Jr., Washington, D. C. assignor of one-half to Charles S. Campbell, Washington, D. C. Filed Sept. 4, 1901. Serial No. 74,600. (No model.)

Claim.—1. In a tool of the character described, the combination with the tubular body, of a longitudinally-movable check, a longitudinally-movable follower or abutment, a spring confined between the check and abutment, means for advancing the follower or abutment as the work progresses, and means for disconnecting the abutment from its advancing means.

2. In a tool of the character described, the combination of the tubular body, the check, the swiveled head, the compression-spring, the screw-check, the divided cone-shaped nut provided with springs adapted to thrust the two parts of said nut out of engagement with the screw-check, and a follower or abutment.

3. In a tool of the character described, the combination of the tubular body, the check, the swiveled head provided with spurs or tangs, the compression-spring and the screw-check and automatically-actuated divided nut.

4. In a tool of the character described, the combination of the tubular body, the check, the swiveled head, the compression-spring, the screw-check, the automatically-actuated divided cone-shaped nut and its follower or abutment.

5. In a tool of the character described, the combination with a tubular body, a longitudinally-movable check, a longitudinally-movable follower or abutment, a spring confined between the check and abutment, means for advancing the follower or abutment as the work progresses, and a longitudinally-adjustable sleeve provided with spurs or tangs, substantially as described.

6. In a tool of the character described, the combination with the tubular body, a longitudinally-movable check, a longitudinally-movable follower or abutment, a spring confined between the check and abutment, means for advancing the follower or abutment as the work progresses, and a longitudinally-adjustable sleeve provided with spurs or tangs, substantially as described.

7. In a tool of the character described, the combination of the tubular body, the check, the swiveled head, the compression-spring, the screw-check, the automatically-actuated divided nut, its follower or abutment, and a collar secured to and surrounding the tubular body and provided with handholds, substantially as described.

8. In a tool of the character described, the combination of the tubular body, the check, a longitudinally-adjustable sleeve provided with spurs or tangs, the head operatively secured to said sleeve, the compression-spring, the screw-check, and the automatically-actuated divided cone-shaped nut and its follower or abutment.

9. In a tool of the character described, the combination of the tubular body, the longitudinally-movable check, a longitudinally-movable follower or abutment, a spring confined between the check and abutment, a ferrule secured in the open end of the tubular body, and means for advancing the follower or abutment as the work progresses.

10. In a tool of the character described, the combination of the tubular body, the longitudinally-movable check, a longitudinally-movable follower or abutment, a spring confined between the check and abutment, a ferrule secured in the open end of the tubular body, means for advancing the follower or abutment as the work progresses, and means for disconnecting the abutment from its advancing means.

696,908. SPEED-REGULATOR FOR GAS-ENGINE. HERBERT H. HENNING, Anderson, Ind. assignor to the Danbury Manufacturing Company, Anderson, Ind. Filed June 27, 1901. Serial No. 65,866. (No model.)

Claim.—1. In a speed-regulating apparatus for a gas-engine, the combination of a pipe leading to the engine-cylinder, a supply-pipe, an open-ended valve-casing connecting these two pipes, a valve working in each open end of this valve-casing, one inward and the other outward and adapted to admit air into both ends of the cylinder-valve casing, a spring tending to open these valves, and means for permitting the valves to open automatically when the speed of the engine increases beyond normal.

2. In a gas-engine, the combination of an open-ended valve-casing interposed in the gas-supply pipe, a valve fitting and working in each open end of the valve-casing, a spring normally tending to open the valves, and means for permitting the spring to act and open the valves when the speed of the engine increases beyond a predetermined degree.

3. In combination with a gas-engine, a shaft operated thereby, spring-actuated governor-weights on said shaft, a flanged sleeve actuated by said governor-weights, supply-pipes for the explosion mixtures and an air-admitting valve in said supply-pipes, means tending to open said valve to admit air, and means normally bearing on the flange carried by said sleeve and adapted to permit the valve to open when said flanged sleeve is actuated.

4. In a speed-regulator for gas-engines the combination of a supply-pipe, an air-admitting valve therein, a spring tending to open this valve, and means adapted to release the valve and permit the spring to open the valve when the speed increases beyond normal.

5. In a speed-regulating apparatus for a gas-engine, the combination of a pipe leading to the engine-cylinder, a supply-pipe, a valve-casing connecting these two pipes and open at both ends, a valve working in each open end of this valve-casing, one opening inward and the other outward and both adapted to admit air into the valve-casing, and means for simultaneously opening these valves when the engine reaches abnormal speed.

696,904. ROTARY ENGINE. HARRIS J. HAWLEY, Kewanee, Ill. assignor of one-half to Alfred M. Hewlett, Kewanee, Ill. Filed Oct. 28, 1902. Serial No. 94,601. (No model.)

Claim.—1. A translating device comprising a casing and a series of rotary members mounted therein and geared together, means for supplying fluid to the interior of the casing intermediate of said members to act on the peripheral faces thereof, and means for leading a fluid into contact with the interior faces of the end members only of the series at points opposite the application of external pressure to said end members.

2. In a device of the character described, the combination with a casing provided with head-blocks and with bearing-plates carried by the opposite end walls of the casing, of rotary pistons located wholly out of contact with the end walls of the casing and having peripheral contact with the head-blocks and bearing at their ends against the bearing-plates, said bearing-plates being disposed across the opposite ends of the steam-space defined between the pistons, to confine the steam to each steam-space.

3. A translating device comprising a casing and a series of rotary pistons, the end pistons of the series being hollow, means for supplying fluid to the interior of the casing intermediate of the pistons, stationary

steam-chests extended into each of the end pistons of the series from opposite sides of the casing, and means for supplying steam to the chests, each of said steam-chests having an open wall opposed to the interior face of its piston.

4. A translating device comprising a casing and a series of rotary pistons, the end pistons of the series being hollow, means for supplying fluid to the interior of the casing intermediate of the pistons, stationary steam-chests of transversely-arcuate form extended into each of the end pistons from the opposite sides of the casing, and means for supplying steam to said chests, each of said steam-chests having an open wall opposed directly to the interior face of its piston.

5. A translating device comprising a casing and a series of rotary pistons, the end pistons of the series being formed with a central web and a cylindrical rim, means for supplying a motive fluid to the interior of the casing intermediate of the pistons, stationary steam-chests of transversely-arcuate form extended into each of the end pistons from the opposite sides of the casing and terminating contiguous to the web, and means for supplying a motive fluid to the chests, each of said chests having an open wall opposed to the interior face of the adjacent piston-rim.

6. A translating device comprising a casing and a series of rotary pistons, the end pistons of the series being hollow, stationary steam-chests extended into the opposite ends of each piston from the opposite sides of the casing, and parts establishing communication between the steam-chests and the steam-space defined intermediate of the pistons, each of said steam-chests having an open wall opposed to the interior face of its piston.

7. In a translating device, the combination with a casing provided with head-blocks and bearing-pistons, of rotary pistons located out of contact with the walls of the casing and having peripheral contact with the head-blocks, and bearing at their ends against the bearing-pistons, and steam-chests extended into the ends of certain of the pistons and provided with open walls opposed to the interior face of the adjacent piston, certain of said bearing-pistons being provided with parts establishing communication between an interior steam-chest and the steam-space defined between contiguous pistons.

8. In a translating device, the combination with a casing, of a rotary center piston provided with heads, a pair of hollow end pistons geared to the center piston and provided with peripheral recesses for the reception of the heads, means for supplying a motive fluid to the interior of the casing intermediate of the pistons, and stationary steam-chests extended into the end pistons and having open walls opposed to the interior face thereof, said end pistons being provided with parts establishing communication between the interior of the casing and the interior of the steam-chests to permit the motive fluid to pass into the steam-chests for application to the interior faces of the end pistons at points opposite the application of external pressure, and means for supplying steam to the steam-chests.

9. In a translating device, the combination with a casing, of a rotary center piston therein provided with heads, a pair of hollow end pistons geared to the center piston and provided with peripheral recesses for the reception of the heads, means for supplying a motive fluid to the interior of the casing intermediate of the pistons, and stationary steam-chests extended into the end pistons and having open walls opposed to the interior face thereof, said end pistons being provided with parts establishing communication between the interior of the casing and the interior of the steam-chests to permit the motive fluid to pass into the steam-chests for application to the interior faces of the end pistons at points opposite the application of external pressure, and means for supplying steam to the steam-chests.

10. In a translating device, the combination with a casing and means for supplying steam thereto, of a rotary center piston therein provided with heads, a pair of hollow end pistons geared to the center piston and provided with peripheral recesses for the reception of the heads, stationary steam-chests extended into the end pistons and having openings opposed to the interior face thereof, head-blocks located within the casing and defining steam-spaces for the passage of the heads, and means for supplying steam to said steam-chests.

11. A translating device comprising a casing and a rotary piston therein, means for introducing steam to the interior of the casing to operate the piston, and steam-chests extending into the piston from the opposite sides thereof.

12. A translating device comprising a casing, and a rotary piston therein, means for leading steam to the interior of the casing, transversely-arcuate steam-chests extending into the piston from the opposite sides thereof, and means for leading steam to the steam-chests.

13. In a translating device, the combination with a casing provided with stationary steam-chests extending laterally from the opposite sides thereof and having open walls, a hollow piston located within the casing and having its peripheral wall disposed opposite the open walls of said steam-chests, and means for leading steam to the casing and steam-chests respectively.

14. A translating device comprising a casing and a hollow piston therein, transversely-arcuate stationary steam-chests extended into the op-

posite ends of the piston from the opposite sides of the casing and having open walls opposed to the peripheral wall of said piston, and means for establishing communication between the steam-chests and the interior of the casing whereby steam may be introduced into one of said chambers for the purpose of supplying both.

15. A translating device comprising a casing and a rotary piston therein formed with a central web and a cylindrical rim, and steam-chests extended into the opposite ends of the piston and bearing against the web thereof.

16. A translating device comprising a casing and a rotary piston formed with a central web and a cylindrical rim, stationary steam-chests of transversely-arcuate form extended into the piston from the opposite sides thereof and bearing at their inner ends against the web, said steam-chests being provided with open walls opposed to the interior face of the cylindrical rim of the piston, means for establishing communication between the casing and steam-chests, and means for leading steam into the casing.

17. A translating device comprising a casing and a plurality of pistons located wholly out of contact with the walls of the casing, bearing-pistons opposed to the ends of the pistons and closing the opposite ends of the steam-spaces defined between the pistons, a head-block having peripheral contact with the pistons, and means for introducing steam to the steam-spaces through the head-block.

18. A translating device comprising a casing and a plurality of pistons located wholly out of contact with the walls of the casing, bearing-pistons opposed to the ends of the pistons and closing the opposite ends of the steam-spaces defined between the pistons, a head-block having peripheral contact with the pistons, means for introducing steam to the steam-spaces through the head-block, and a stationary steam-chest extending into the piston and provided with an open wall disposed opposite the interior face of the piston-rim.

19. A translating device comprising a casing and a plurality of pistons, a stationary steam-chest located within one piston, means for introducing steam to the interior of the casing, and a port located beyond the end of the piston and communicating at its opposite ends with the interior of the casing and steam-chest respectively.

20. In a translating device, the combination with a casing and a piston, said piston being composed of a hub, a web and a cylindrical rim, of stationary steam-chests located between the hub and rim and abutting against the web of the piston.

21. A translating device comprising a casing, a series of rotary pistons arranged in alignment within the casing and moving in unison, means for supplying fluid to the interior of the casing intermediate of said pistons to act on the peripheral faces thereof, steam-chests mounted within the end pistons only of the series and having open walls opposed to the interior faces of said end pistons at points opposite the application of external pressure thereto, and means for supplying steam to said steam-chests.

22. In a translating device, the combination with a casing provided with head-blocks, and with bearing-pistons rigidly connected to the inner faces of the opposite end walls of the casing and disposed immediately adjacent to the head-blocks, of rotary pistons located wholly out of contact with the end walls of the casing and having peripheral contact with the head-blocks, and bearing at their ends against the bearing-pistons, said bearing-pistons being disposed entirely across the opposite ends of the steam-spaces defined between the pistons to confine the steam to said steam-spaces and thus prevent the application of steam-pressure to the ends of the pistons.

696,805. APPARATUS FOR APPLYING FLUID-PRESSURE.
WARREN S. JOHNSON, Milwaukee, Wis., assignor to Johnson Electric Service Company, Milwaukee, Wis., a Corporation of Wisconsin. Filed Aug. 9, 1900. Serial No. 26,242. (No model.)

Claim.—1. In apparatus for applying fluid-pressure the combination of an expandable chamber having supply, service and waste ports and

a movable part exposed on one side to service-pressure, valve mechanism controlling the supply and waste ports and adapted to be operated by said movable part, a variable yielding resistance acting on said movable part in opposition to the service-pressure, means for varying said resistance by predetermined degrees and means for positively holding the valve mechanism in position to admit supply-pressure to the service-port independently of said yielding resistance, substantially as and for the purposes set forth.

2. In apparatus for applying fluid-pressure the combination of an expandable chamber having supply, service and waste ports and a movable part exposed on one side to service-pressure, valve mechanism controlling said supply and waste ports and adapted to be operated by said movable part, a spring acting on said movable part in opposition to the service-pressure, means for varying the tension of said spring by predetermined degrees, and means for positively shifting said movable part to open the supply-port independently of said spring, substantially as and for the purposes set forth.

3. In apparatus for applying fluid-pressure the combination of an expandable chamber having supply, service and waste ports and a movable part exposed on one side to service-pressure, valve mechanism controlling said supply and waste ports and adapted to be operated by said movable part, a spring on said movable part in opposition to the service-pressure, a screw for varying the tension of said spring, and a clutch for positively connecting said screw and movable part when the spring is compressed to a certain degree, substantially as and for the purposes set forth.

4. In apparatus for applying fluid-pressure the combination of an expandable chamber having supply and service ports and a movable part exposed on one side to service-pressure, a valve controlling said supply-port, having a waste-passage leading through it from said chamber to the atmosphere, a spring normally holding said valve against its seat, a variable yielding resistance acting in opposition to the service-pressure on said movable part which is constructed and arranged to open the supply-valve and to close the waste-passage through it, and means for manually varying said resistance by predetermined degrees, substantially as and for the purposes set forth.

5. In apparatus for applying fluid-pressure the combination of an expandable chamber having supply, service and waste ports and a movable part exposed on one side to service-pressure, valve mechanism controlling said supply and waste ports, and adapted to be operated by said movable part, a screw working in a fixed nut, and provided with a cam or incline, a spring interposed between said screw and movable part, and a part interposed between said movable part and the cam or incline on said screw and adapted, when said spring is compressed to a certain degree by said screw, to positively act on said movable part and valve mechanism independently of said spring, substantially as and for the purposes set forth.

6. In apparatus for applying fluid-pressure the combination of an expandable chamber having supply, service and waste ports and a movable part which is exposed on one side to service-pressure, valve mechanism controlling said supply and waste ports and adapted to be operated by said movable part, a hollow screw working in a fixed nut and provided with a cam or incline, a yoke guided in said nut and bearing at one end against said movable part and projecting at the other end into the path of said cam or incline, a bolt passing axially through and adjustably fastened in said screw and passing through an opening in said yoke and bearing at one end against said movable part, a spring held on said bolt in said screw and bearing at one end against the screw and at the other end against an abutment on the bolt, and a crank for turning said screw, substantially as and for the purposes set forth.

7. In apparatus for applying fluid-pressure the combination with a source of fluid-pressure and a fluid-pressure motor, of a controlling device comprising an expandable chamber having a waste-port and supply and service ports connected with said source of pressure and with said motor, respectively, valves normally closing said supply and waste ports, a movable part exposed on one side to service-pressure and adapted to open either valve when the other valve is closed, a spring adapted to act on said movable part in opposition to the service-pressure, a screw acting on said spring, means for manually turning said screw and varying the pressure of said spring on said movable part, and means operated by said screw for positively opening the supply-valve and holding it open when said spring is compressed to a certain degree, substantially as and for the purposes set forth.

8. In apparatus for applying fluid-pressure the combination with a source of fluid-pressure and a fluid-pressure motor, of a controlling device comprising an expandable chamber having a waste-port and supply and service ports connected with said source of pressure and with said motor, respectively, valves normally closing said supply and waste ports, a movable part exposed on one side to service-pressure and adapted to open either valve when the other valve is closed, a spring adapted to act on

said movable part in opposition to the service-pressure, a screw acting on said spring and provided with a cam or incline, a handle for turning said screw and compressing said spring to predetermined degrees, means for permanently adjusting the tension of said spring independently of said handle, and a part actuated by said cam or incline for positively opening and holding open the supply-valve independently of said spring when said handle is moved to its limit in one direction, substantially as and for the purposes set forth.

696,806. WIRE REELING AND STRETCHING MACHINE.
HENRY C. LAMB, Boston, Mass. Filed Aug. 14, 1901. Serial No. 73,066. (No model.)

Claim.—1. In a machine of the class described, the combination with a wagon having a framework located at the rear end of the body, wire-carrying spools mounted on the framework, a series of vertically-adjustable guides mounted on the framework and located in rear of the wire-carrying spools, and a vertical series of wire-stretching devices also mounted on the framework, substantially as described.

2. In a machine of the class described, the combination of a wagon having a framework extending from the rear portion of the wagon-body and provided with spindle-rods adapted to receive spools of wire, a vertical rod located in rear of the spindle-rods and provided at intervals with wire-receiving guides, said guides being adjustably secured to the vertical rod and capable of vertical adjustment, and means for stretching a series of wires, substantially as described.

3. In a frame-making machine the combination of a body having a rearwardly-extending framework which extends above and below the plane thereof and comprising upper and lower plates and an intermediate platform to support an operator, and wire feeding and stretching devices disposed in said framework.

4. In a frame-making machine, the combination of a wagon-body having an upright at the rear portion thereof, a framework supported by said upright and rear portion of the body and extending outwardly to the rear from the latter, an arch-brace secured to the body, upright and rear portion of the framework, and wire feeding and stretching devices carried by said framework.

696,807. ADVERTISING-WAGON. JAMES LAMBERTSON, Reading, Pa., assignor of three-eighths to Charles W. Keller, Benjamin F. Pflum, William K. Kaufmann, and John E. Herringer, Reading, Pa. Filed June 28, 1901. Serial No. 66,010. (No model.)

Claim.—1. The combination with the bed, of the front and rear vertical roll-columns, centrally located transversely, the bearings on the bed for said columns, shaft extensions of the columns below said bearings, the horizontal shaft under said bed between said shaft extensions, the trans-

verse operating-shaft arranged to engage said horizontal shaft to rotate the latter in one direction or the other, and mechanism for throwing said horizontal shaft into rotating engagement with one or other of said shaft extensions, substantially as set forth.

2. The combination with the bed and the vehicle running-gear comprising a rotary rear axle, of the front and rear vertical roll-columns located centrally thereon transversely, the bearings on the bed for said columns, shaft extensions of the columns below said bearings, the horizontal shaft under said bed between said shaft extensions, the transverse operating-shaft arranged to engage said horizontal shaft to rotate the latter in one direction or the other, mechanism for throwing said horizontal shaft into rotating engagement with one or other of the columns, and operating mechanism for said transverse shaft connecting with said rotary axle, substantially as set forth.

3. The combination with the bed and the column bearing-ring fixed thereto, of the roll-column having a central shaft extending below the base-plate thereof, a bearing-disk fixed to said shaft extension below said base-plate, a ball-race formed in the meeting faces of said fixed bearing-ring and rotary bearing-disk, and guide-rollers mounted in brackets fixed to the bed and overhanging said bearing-disk, substantially as set forth.

4. The combination with the bed and the column bearing-ring fixed thereto, of the roll-column having a central shaft extending below the base thereof, and above the roll-column, operating mechanism for said roll-column located beneath the bed and arranged to engage said shaft extension, and a roof-frame mounted upon said upward extension of the column-shaft and serving to maintain a uniform spread of the columns and thereby relieve the bottom bearings of the latter substantially as set forth.

5. The combination with the bed and the two vertical roll-columns rotatably mounted thereon and having central shafts with upward extensions above the columns, of a roof-framing comprising inclined rafters loosely mounted upon said shaft extensions, and horizontal pin-bars connecting said loosely-mounted rafters to form a rigid roof-frame between the column-shafts supporting the same, substantially as set forth.

6. The combination with the bed and the two vertical roll-columns rotatably mounted thereon and having central shafts with upward extensions above the columns, of a roof-framing mounted upon said shaft extensions, a curved roof-covering depending on either side below the rafters of the roof-framing toward the bed to form side walls, and a brace or braces pivoted at one end to the bed and adapted when raised to engage and support the free lower edges of the curved covering in elevated and laterally-projected position, substantially as set forth.

696,908. SEPARABLE TROUSERS-BUTTON. ALEXANDER LEWIS, Lakeland, Fla. Filed July 26, 1901. Serial No. 66,513. (No model.)

Claim.—1. An improved article of manufacture the herein-described separable trousers-button, consisting of the half-disk A and A', the necks or shanks B and B', the clamp-plates C and C', each of said clamp-plates being provided on the outer upright edges of its respective face and back with series of teeth d and d', said clamp-plates also having respectively a rectangular aperture e and a prong f, the aperture e being provided to receive the prong f of clamp-plate C', in substance as set forth.

2. A separable trousers-button, made up of two sections, one of said sections embracing the downward-extending half disk or head A', joined to the clamp-plate C' by the neck or shank B', said clamp-plate having on the back and outer upright edges series of teeth d', and an inwardly-projecting prong f, bent at f' to any suitable angle and extending downward in a plane parallel to the clamp-plate C'; and the other section embracing the upward-extending half disk or head A joined to the clamp-plate C by the neck or shank B, said clamp-plate having on its face and outer upright edges series of teeth d, and a rectangular aperture e provided near its lower end to receive the prong f, all combined as and for the purpose shown and set forth.

696,909. CARBURETING DEVICE FOR EXPLOSIVE-ENGINE. THOMAS MCGOWAN and ARTHUR D. HILLER, Mount Pleasant, Pa., assignors of one-fourth to Samuel J. Hiller, Mount Pleasant, Pa. Filed Jan. 24, 1901. Serial No. 64,501. (No model.)

Claim.—1. The combination with a vapor-engine, of a carburator comprising a carburating-chamber and a vapor-chamber, means for passing a heated fluid through, but not into, said chambers, means for liberating said fluid within the carburating-chamber, means for leading the carburated fluid through the carburating-chamber into the vapor-chamber, and means for leading the vapor or gas from the vapor-chamber to the engine for consumption.

2. The combination with a vapor-engine, of a carburator comprising a carburating-chamber and a vapor-chamber communicating therewith, a heating-tube extending through said chambers, means for establishing communication between one end of said tube and the interior of the carburating-chamber, means for leading a heated fluid through the tube to heat said chambers prior to the delivery of said fluid to the interior of the carburating-chamber, and means for leading the gas or fluid from the vapor-chamber to the engine.

3. The combination with a vapor-engine, of a carburator comprising an exhaust-chamber, a vapor-chamber and an intermediate carburating-chamber, of means for leading the exhaust from the engine into the exhaust-chamber of the carburator, means for leading the exhaust fluid from the exhaust-chamber to the interior of the carburating-chamber, means for establishing communication between the carburating-chamber and the vapor-chamber, and means for leading the gas or vapor from the vapor-chamber to the engine for consumption.

4. The combination with a vapor-engine having an explosion-chamber and an igniter-burner, of a carburator comprising a plurality of vapor-chambers disposed to supply vapor to the explosion-chamber and igniter-burner, respectively, carburating-chambers in communication with said vapor-chambers, an exhaust-chamber disposed to receive the exhaust fluid from the engine, and having communication with the interior of each of the carburating-chambers, and means for leading the exhaust through the vapor-chambers before delivery to the carburating-chambers, whereby the tension of the vapor is raised prior to its delivery to the engine.

5. In a carburator, the combination with a casing comprising an exhaust-chamber, carburating-chambers and vapor-chambers, of means controlling communication between the carburating-chambers and the vapor-chambers, means for applying a fluid under pressure to the exhaust-

chamber, means for leading said fluid from the exhaust-chamber to the carburating-chambers and for leading said exhaust fluid through the carburating-chambers before delivery thereto, and means for leading the vapor from the vapor-chambers.

6. In a carburator, the combination with a casing subdivided to define a pair of carburating-chambers, vapor-chambers above and an exhaust-chamber below the carburating-chambers, of means located within the carburating-chambers and extended into the vapor-chambers, heating-tubes extending from the exhaust-chamber through the carburating and vapor chambers, filling-tubes extending through the vapor-chambers and opening into the carburating-chambers, and means for establishing communication between the upper ends of the heating and filling tubes.

7. In a carburator, the combination with a casing having an apertured partition defining a carburating-chamber and a vapor-chamber at opposite sides thereof, of cylindrical walls located in the carburating-chamber and extended into the apertures of the partition, short wick-tubes disposed within the upper ends of the walls, and means for leading a fluid through the carburator.

696,910. NOTE-SHEET OR MUSIC-BOOK. JOSEPH WATTEBER, Jersey City, N. J., assignor to Parthenon Music Box Company, Newark, N. J., a Corporation of New Jersey. Filed Apr. 22, 1901. Serial No. 57,864. (No model.)

Claim.—1. A tooth for note-sheet, located opposite and formed of the metal from an opening in said sheet, and composed of an upright shoulder and an inclined back integral with each other and with the sheet, said shoulder being of approximately the same thickness as the body of the sheet, and said back of a less thickness, and said shoulder being connected at one end with the back and at the other end with the sheet, substantially as set forth.

2. A tooth for note-sheet, located opposite and formed of the metal from an opening in said sheet, and composed of an upright shoulder and an inclined and hardened back integral with each other and with the sheet, said shoulder being of greater thickness than said back, and connected at one end therewith and at the other end with the sheet, substantially as set forth.

3. A tooth for note-sheet, located opposite and formed of the metal from an opening in said sheet, and composed of an upright shoulder and an inclined and hardened back integral with each other and with the sheet, said shoulder being of greater thickness than said back, and connected at one end therewith and at the other end with the sheet, substantially as set forth.

4. A tooth for note-sheet, located opposite and formed of the metal from an opening in said sheet, and composed of an upright shoulder and an inclined and hardened back integral with each other and with the sheet, said shoulder being of approximately the same thickness as the body of the sheet, and said back of a less thickness, and said shoulder being connected at one end with the back and at the other end with the sheet, substantially as set forth.

5. A note-sheet having openings, and teeth located each opposite one of said openings, and formed of the metal of the same, and composed of an upright shoulder and an inclined back integral with each other and with the sheet, said shoulder being of approximately the same thickness as the body of the sheet, and said back of less thickness, and said shoulder being connected at one end with the back and at the other end with the sheet, substantially as set forth.

696,911. HOSE-SUPPORTER. GEORGE H. PHILLIPS, Boston, Mass., assignor to George Frost Company, Boston, Mass., a Corporation of Massachusetts. Filed Nov. 22, 1901. Serial No. 21,026. (No model.)

Claim.—1. A gutterman's gutter comprising a clamp, a supporting-rod stretched thereon, a band, to one end of which the rod is permanently connected, and a hook attached to the band having an upturned lower end, and provided with a curved wearing-surface for the rod, arranged above and extending beyond both side edges of the bottom of the hook, the widest part of the wearing-surface being substantially at the bottom of the hook.

2. A hook for gutter, comprising a rear portion, a bottom portion and a front portion, which latter extends laterally from both sides of the central longitudinal axis of the back portion, in combination with a stationary curved wearing-piece, secured to the back, and extending laterally beyond both side edges thereof, the widest portion of said curved wearing-piece being substantially at the bottom of the hook, while the curved wearing-surface of the wearing-piece is arranged above the bottom of the hook.

696,912. HOSE-SUPPORTER. CHARLES J. ROSE, Calcutta, Ill., assignor to Adelle H. Rose, Calcutta, Ill. Filed May 24, 1897. Serial No. 57,890. (No model.)

Claim.—1. In hose-supporters, the combination with the webbing, of a metal loop having a contracted end portion and an engaging button each secured to said webbing, whereby the hose is held by said button in the contracted end of said loop, said loop being formed of a folded sheet-metal blank having sections with coincident openings therein, and a flat blank, of uniform thickness and of soft, flexible material, interposed between said folded sections and having a central opening smaller than but conforming in outline to the openings in said sections, said metal loop being provided with means for preventing the lateral displacement in either direction of said flexible blank, substantially as described.

2. In hose-supporters, the combination with the webbing, of a metal loop having a contracted end portion and an engaging button each secured to said webbing, whereby the hose is held by said button in the contracted end of said loop, said loop being formed of a folded sheet-metal blank having sections with coincident openings therein, and a flat blank, of uniform thickness and of soft, flexible material, interposed between said folded sections and having a central opening smaller than but conforming in outline to the openings in said sections, the metal of said loop being indented or crimped to prevent the lateral displacement in either direction of said flexible blank, substantially as described.

3. In hose-supporters, the combination with the webbing, of a metal loop having a contracted end portion and an engaging button each secured to said webbing, whereby the hose is held by said button in the contracted end of said loop, said loop having an elongated transverse opening at the larger end and being formed of a folded sheet-metal blank having symmetrical sections connected at the contracted end and with coincident openings therein, and a flat blank, of uniform thickness and of soft, flexible material, interposed between said folded sections and having a central opening smaller than but conforming in outline to the openings in said sections, said metal loop being provided with means for preventing the lateral displacement in either direction of said flexible blank, substantially as described.

696,913. CONCENTRATOR. WILLIAM E. SULLIVAN, Denver, Colo., assignor of fifty-nine one-hundredths to Oscar C. Ratten, George T. Ratten, and C. A. Richmond, Denver, Colo. Filed Aug. 24, 1899. Serial No. 27,904. (No model.)

Claim.—In combination, a fixed table having an inclined surface with a fixed trough about the same deeper at one point than at another, a pair of gates at the deeper part of the trough, said gates being in different planes, a pedestal 6 provided with a series of steps, a vertical shaft extending from said pedestal and journaled therein, the stationary frame 10 in which the said shaft is journaled at its upper end, the screws connected to the shaft, the drags carried by the screws to move over the table, a hopper carried by the screws and surrounding the shaft, said hopper directing the material onto the slope of the pedestal, a trough for

directing the material to the hopper and means for driving the shaft, substantially as described.

698,914. VENTILATING APPARATUS. LEON S. SWANSON, Springfield, Mass., assignor of one-half to August C. J. Swanson, Springfield, Mass. Filed May 26, 1901. Serial No. 61,872. (No model.)

Claim.—1. A flaring downwardly-open hood, for employment above a range, having therewithin a horizontal partition provided with a ventilating-opening *b*, and also with an aperture *c*, and said hood having a passage leading from an upper portion thereof, combined with a plate or closing-door, for said opening *b*, hinged to the partition adjacent the latter opening, and having a spring for normally forcing the door to its closed position, a cheave mounted within the hood above said partition, a flexible connection secured to a free edge portion of the door, having a guiding engagement around said cheave, and extended downwardly from the latter through said aperture *c* to a position below the hood, substantially as described.

2. A structure having the studs or bolts, the removable sectional wall, having the opening *b*, engaging over said studs and confining means therefor, the door hinged to said wall, the bracket mounted on said wall and provided with the cheave, and the chain secured to a free portion of the door and guided over the cheave to an accessible position for operation.

3. In an apparatus of the character described, the combination with the wall *a* having a ventilation-opening *b*, and provided with car-legs *j* and bracket *p*, of the plate or door *m* having the car-legs *k*, the hinge-rod *n*, the spring having intermediate U portion 10, aligned coils 12, 12, surrounding the rod and the oppositely-extended end portions 13, the cheave *q* in said bracket, and the chain *a*, secured to a free portion of the door and thence guided over said cheave to a convenient place to be drawn upon, all substantially as described.

4. In an apparatus of the character described, the combination with a permanent wall having the bolts or screw-studs *ff*, of the removable wall *a* having the perforations *g g*, a ventilation-opening *b*, and provided with car-legs *j* and bracket *p*, the nuts *h h*, the plate or door *m* having the car-legs *k*, and the perforation *t*, the hinge-rod *n*, the spring having intermediate U portion 10, aligned coils 12, 12, surrounding the rod, and the oppositely-extended end portions 13, the cheave *q* in said bracket, and the chain *a*, secured to a free portion of the door and thence guided over said cheave and through said perforation *t* to a convenient place to be drawn upon, and the confinement-end *v* adjacent the free end of the chain, all substantially as described and shown.

698,915. GRAIN-SEPARATOR. FRED WHITE, OMAHA, ILL. Filed Nov. 24, 1900. Serial No. 57,064. (No model.)

Claim.—1. In a shoe for grain-separators, the combination with the frame thereof provided at its rear end with a tail-board spout, of an upper riddle spaced above said spout and having its rear end projecting over the spout, a screen arranged at the bottom of the frame and having its rear end in contact with the forward edge of said spout, said screen inclining forwardly and downwardly from the spout, and a lower riddle interposed between the upper riddle and the screen, said lower riddle being inclined reversely to the screen and having its rear end resting upon

the forward edge of the tail-board spout and its forward end in close contact with the upper riddle, whereby the tailings discharged from the upper riddle are received by the lower riddle and deflected thereby from the screen into the tail-board spout.

2. In a shoe for grain-separators, the combination with the frame thereof provided at its rear end with a tail-board spout, of an upper riddle spaced above said spout and having its rear end projecting over the spout, a screen arranged at the bottom of the frame and having its rear end in contact with the forward edge of said spout, said screen inclining forwardly and downwardly from the spout, and a lower riddle interposed between the upper riddle and the screen, said lower riddle being inclined reversely to the screen and having its rear end resting upon the forward edge of the tail-board spout and its forward end in close contact with the upper riddle at a point intermediate the ends of the latter, whereby the tailings discharged from the upper riddle are received by the lower riddle and deflected thereby from the screen into the tail-board spout.

698,916. APPARATUS FOR GAGING TEMPERATURES OF HEATED SUBSTANCES. EUGENE F. MOORE, TRUMBURG, N. Y. Filed Nov. 2, 1900. Serial No. 734,502. (No model.)

Claim.—1. In an apparatus for gaging the temperature of substances which become incandescence when heated, the combination of the standard, means for supporting the same in line with the substance to be tested and the eye so that a portion at least of one may be superposed upon the field of the other, and means for bringing those portions thereof which are directly under the eye of the observer to practically the same appearance.

2. In an optical heat-gage apparatus, means for furnishing an optical standard of comparison with the substance to be heated and so located in the apparatus as to permit at least a portion of one to be seen superposed upon the field of the other.

3. In a heat-gage apparatus, an optical standard consisting of a substance that may be made incandescence and so located in the apparatus as to be in the path of the rays passing to the eye from the heated substance to be tested or gaged.

4. In an apparatus for gaging the temperature of a substance, a standard adapted to become incandescence to a degree corresponding to the incandescence of said substance when heated to the desired temperature, said standard being so located with respect to the line of vision through the apparatus as to permit a portion at least of one to be seen superposed upon the field of the other.

5. An optical heat-gage having an optical standard consisting of a substance whose degree or nature of incandescence is dependent upon the temperature to which it is heated and so located in the apparatus as to permit at least a part of its incandescence to be seen superposed upon the field of the incandescence of the heated substance to be tested or gaged.

6. The combination with two incandescent lamps 13 and 14, a rheostat and ammeter in the circuit of one lamp, a rheostat in the circuit of the other lamp, and a reversing switch for transposing the circuits of the lamps substantially as and for the purpose set forth.

696,917. NON-REFILLABLE AND NON-REMITTABLE VESSEL FOR LIQUIDS. ROBERT F. YER, New York, N. Y. Filed Sept. 20, 1901. Serial No. 78,972. (No model.)

Claim.—1. The combination of a vessel for liquids, having in the neck or corresponding passage thereof an annular groove, with a casing having compressible spring-plugs adapted to engage said groove, said casing having recesses at each side, and a circular interior chamber having an inlet-passage, leading from the body, and an outlet-passage protected by a perforated cap, leading to the mouth of the vessel, with a transverse shaft carrying blades within said chamber, adapted to rotate by liquid-pressure and to control inlet and outlet passages, said shaft being also provided at one end with a rigid pulley, *p*, which is connected by a cord with another pulley, *q*, so that revolving of the shaft causes the cord to be unwound from pulley *q*, and simultaneously wound onto pulley *p*, and said shaft being further provided at the other end with a rotary clutch and corresponding revolvable loops adapted to prevent reversing revolutions, substantially as shown and described.

2. The combination of a vessel for liquids, having a neck or other

corresponding passage, with a transverse shaft carrying blades adapted to rotate by liquid-pressure and to control inlet and outlet, said shaft being also provided with a rigid pulley *p*, which is connected by a cord with another pulley *q*, so that revolving of the shaft causes the cord to be unwound from pulley *q* and simultaneously wound onto pulley *p*, and said shaft being further provided with a rotary clutch and corresponding revolvable loops adapted to prevent reversing revolutions, substantially as shown and described.

3. The combination of a tube or conduit with a transverse shaft carrying blades adapted to rotate by liquid-pressure and to control inlet and outlet, said shaft being provided with a rigid pulley *p*, which is connected by means of a cord or chain (of length only to allow sufficient revolutions for the valve to open and pass the stipulated quantity) with another pulley *q* so that revolving of the shaft causes the cord or chain to be unwound from pulley *q* and simultaneously wound onto pulley *p*, and said shaft being further provided with a rotary clutch and corresponding revolvable loops adapted to prevent reversing revolutions, thereby automatically measuring and cutting off supplies, substantially as shown and described.

4. A device to limit revolutions and check reversing motion of a shaft, comprising a pulley *p* rigid on said shaft, connected, by means of a cord or chain, of length only to allow of limited number of revolutions with another pulley *q*, so that revolving of the shaft causes the cord or chain to be unwound from pulley *q*, and, simultaneously, wound onto pulley *p*, said chain being checked by the fastened end at pulley *q*; together with a rotary clutch, having one or more hook-shaped arms, carried rigid on said shaft so as to engage one or more of a series of revolvable loops mounted in proper position for reciprocal service, said clutch and revolvable loops being so located in relation to each other as to be always within interlocking range, so that, when said clutch is rotated in one direction, the resulting collision with the series of revolvable loops causes said loops to revolve and allow the clutch to clear for further rotation, but, when said clutch is rotated in the reverse direction, it must interlock with the revolvable loops, and thus break all rotation in that direction substantially as shown and described.

5. A device to limit revolutions of a shaft comprising a pulley *p* rigid on said shaft connected by means of a cord or chain of length to allow of limited number of revolutions with another pulley *q*, so that revolving of the shaft causes the cord or chain to be unwound from pulley *q*, and simultaneously, wound onto pulley *p*, said chain being checked by the fastened end at pulley *q*, substantially as shown and described.

6. A non-refillable vessel for liquids comprising the vessel or frame *A*, having in its neck the annular groove *f*; the casing *B* inserted therein and held in position by the spring-plugs *g* engaging groove *f*, said casing having side recesses *d* and *e*, a circular interior chamber *a*, outlet-passage *b*, and inlet-passage *c*; the transverse shaft *h* mounted within said casing, passing through chamber *a*, and extending into recesses *d* and *e*, said shaft carrying, in chamber *a*, the blades *m* *n*, adapted to rotate by liquid-pressure and to control inlet and outlet, also carrying, in recess *d*, the rigid pulley *p*, connected by the cord *r* to the other pulley *q*, said cord having first been securely attached, at one end, to pulley *q* then wound on same, as many times as original contents passing through chamber *a* rotates the blades *m* *n*, and then out and attached, at that end, to pulley *p*, said shaft further carrying or engaging, in recess *e*, the rotary clutch *y* and the loops *z* adapted to interlock and prevent reverse revolution of the shaft, the whole being adapted so that pressure of the originally-enclosed liquid on the blades causes the shaft to revolve and the blades to rotate until the cord is unwound from pulley *q* and, simultaneously, wound onto pulley *p*, till the fastened end at pulley *q* stops rotation, so that original contents can flow out freely, but, should the vessel be afterward wholly or partially refilled, by any means, refilling is prevented by restraint of the cord *r*, in recess *d*, and obstruction of the clutch *y* and loops *z*, in recess *e*, which prevent any further rotation of the blades controlling the outlet, substantially as shown and described.

7. In a non-refillable vessel for liquids the frame *A* having a neck or similar passage; inserted in said neck the casing *B* having inlet and outlet passages therein; covering said outlet-passage the protecting perforated cap *i*; attached to said casing the retaining-plugs *g* engaging in the annular groove *f*; mounted within said casing the shaft *h*; carried on said shaft the blades *m* *n* controlling inlet and outlet passages; carried on said shaft the pulley *p* and the clutch *y*; mounted in position to correspond with said clutch the revolvable loops *z*; connected by the regulating-cord with said pulley *p*, the additional pulley *q*; the cord *r* connecting said pulleys *p* and *q*, all adapted for the purposes named, substantially as shown and described.

REISSUES.

11,978. MOWING-MACHINE ATTACHMENT. THOMAS B. FAGAN, Van Wert, Ohio, assignor, by mesne assignments, to the Side Delivery Reaper Company, Toledo, Ohio, a Corporation of Ohio. Filed Jan. 29 1902. Serial No. 81,808. Original No. 948,948, dated Feb. 6, 1900.

Claim.—1. A side-delivery attachment for mowing-machines, comprising in its construction a plurality of thin, resilient ribs gradually and uniformly increasing in length from one side to the other of the attachment and having their front portions in a substantially uniform flat plane to rest on the ground, and having their rear portions turned upwardly and twisted in a direction to present their concave faces toward the longer or discharge side of the attachment.

2. The combination with a mower having a side-delivery gatherer comprising a series of bars extending rearwardly from the finger-bar and having upwardly-turned free ends, of a gate parallel with the delivery side thereof and movably supported to enable it to be moved away to permit the discharge of a bunch of grass.

3. In a mower, the combination with a gatherer arranged behind the cutter-bar and composed of parallel ribs turned up at their rear ends on a diagonal line; of a gate composed of an arm having pendant teeth or tines arranged along the line of draft parallel with the delivery side of the gatherer, said arm being made adjustable to be lifted from the gatherer to discharge the bunch of grass substantially as described.

4. The combination with a mower having a gatherer with a side delivery; of a variably-working gate having revolving pendant prongs or teeth curved at their lower ends substantially as and for the purpose described.

11,979. ASHAYER'S FURNACE. JOHN J. LEONARD and ALBERT C. GALKIN, Los Angeles, Cal., assignors, by mesne assignments, to F. W. Brown & Company, Los Angeles, Cal. Filed Feb. 14, 1902. Serial No. 796,516. Original No. 698,888, dated Aug. 9, 1900.

Claim.—1. An ashayer's furnace consisting of a furnace-body, a muffle therein provided with a draft-opening, and draft-inducing means exteriorly of the furnace-body in communication with the draft-opening of the muffle.

2. An ashayer's furnace consisting of a furnace-body provided with an opening and a draft-flue, a muffle within said body provided with a draft-opening, and draft-inducing means exteriorly of the furnace-body, communicating respectively with the draft-opening of the muffle through the furnace-wall, and with the draft-flue.

3. An ashayer's furnace consisting of a furnace-body provided with an opening and a draft-flue, a muffle in the body provided with a draft-opening in communication with the opening in the furnace, a conduit exteriorly of the furnace-body communicating respectively with the draft-opening of the muffle through the furnace-wall, and with the draft-flue, and means within said conduit for regulating the draft through the muffle.

4. An ashayer's furnace consisting of a furnace-body provided with an opening and with a draft-flue, a muffle in the body provided with a draft-opening in communication with the opening in the furnace-wall, and a thin-walled draft-inducing means exteriorly of the furnace in communication respectively with the muffle through the furnace-wall and with the furnace-flue.

5. An ashayer's furnace consisting of a furnace-body provided with an opening and a draft-flue, a muffle in the body provided with a draft-opening in communication with the opening in the furnace-wall, a sheet-metal pipe communicating with the opening in the furnace-wall and with the flue, and a damper in said pipe for regulating the draft through the muffle.

6. The improved ashayer's furnace, adapted for burning gasolene or other hydrocarbon, the same comprising the body or casing, having the rear horizontal passage 2, the muffle having a rear opening registering with such passage, the rear tubular extension or bon 3, the main flue attached to top of the furnace, and the existing attachment, consisting of the exterior pipe 4, connecting the above-mentioned bon and main flue, and provided with a damper, as shown and described.

7. The improved ashayer's furnace, comprising the body having the rear passage 2, the muffle arranged with its lower end provided with an opening and separated from the rear wall of said body, save where the passage and opening coincide, the main flue, and the existing attachment consisting of an exterior pipe which connects the above-mentioned passage and main flue, as shown and described.

DESIGNS.

85,829. SPOON. FRANK P. FARMY, Kalamazoo, Mich. Filed Jan. 27, 1902. Serial No. 81,622. Term of patent 14 years.

Claim.—The design for a spoon or the article, as herein shown and described.

85,880. GLASS DISH. WILLIAM C. ANDERSON, Chicago, Ill., assignor to the Libbey Glass Company, Toledo, Ohio, a Corporation of Ohio. Filed Mar. 10, 1902. Serial No. 87,642. Term of patent 7 years.

Claim.—The design for a glass dish as herein shown and described.

85,881. PICTURE-FRAME. EARL GEORGE, Newark, N. J. Filed Mar. 1, 1902. Serial No. 86,366. Term of patent 7 years.

Claim.—The design for a picture-frame herein shown and described.

85,882. CLOCK-CASE. HENRY JACOB, St. Louis, Mo. Filed Dec. 21, 1901. Serial No. 87,973. Term of patent 14 years.

85,882.

Claim.—The design for a clock-case as herein shown and described.

85,883. VIOLIN-CASE. FRANK E. KENNEDY, Newark, N. J., assignor to Washburn & Whittemore, Newark, N. J. Filed Feb. 5, 1902. Serial No. 86,751. Term of patent 14 years.

Claim.—The design for a violin-case as herein shown and described.

85,884. LAMP-FIXTURE. THOMAS MOORE JAMES, Memphis, Tenn. Filed Mar. 1, 1902. Serial No. 86,366. Term of patent 14 years.

85,884.

Claim.—The design for a lamp-structure, substantially as herein shown and described.

85,885. GAS-ARC LIGHT. HERMAN E. FRANK, Milwaukee, Wis.
Filed Feb. 20, 1902. Serial No. 54,353. Term of patent 7 years.

Claim.—The design for a gas-arc light, as herein shown and described.

85,886. GEAR-CASEING. CHARLES WALLACE HUNT, West New Brighton, N. Y. Filed Feb. 14, 1902. Serial No. 53,126. Term of patent 14 years.

Claim.—The design for a gear-caseing, substantially as shown and described.

85,887. WALL-CASEING. CHARLES E. LARRABEE, Oakland, Cal.
Filed Apr. 16, 1901. Serial No. 53,128. Term of patent 7 years.

Claim.—The design for a wall-caseing substantially as herein shown and described.

85,888. FONT OF PRINTING-TYPE. HERMAN ILLINGHAM, Philadelphia, Pa., assignor to the American Type Foundry Company, Newark, N. J., a Corporation of New Jersey. Filed Mar. 5, 1902. Serial No. 94,874. Term of patent 14 years.

ABCDEFGHIJKLMNNOQRSTUVWXYZ

XYZA BCDEFGHIJKLMNOPQRSTUVWXYZ

abcdefghijklmnopqrstuvwxyz

Claim.—The design for a font of printing-type as herein described and as illustrated in the accompanying typographical impression.

85,889. FONT OF TYPE. JAMES W. FLETCHER, Hartford, Conn., assignor to the American Type Foundry Company, New York, N. Y., a Corporation of New Jersey. Filed Feb. 3, 1902. Serial No. 94,267. Term of patent 14 years.

ABCDEFGHIJKLMNNOQRSTUVWXYZ

XYZA

abcdefghijklmnopqrstuvwxyz

123456789

Claim.—The design for a font of type as herein shown and described.

85,840. APPAREL-BELT. OTTO A. LUNNAR, Hoboken, N. J. Filed Mar. 8, 1902. Serial No. 97,396. Term of patent 34 years.

Claim.—The design for an apparel-belt, substantially as herein shown and described.

85,841. APPAREL-BELT. OTTO A. LUNNAR, Hoboken, N. J. Filed Mar. 8, 1902. Serial No. 97,396. Term of patent 34 years.

Claim.—The design for an apparel-belt, substantially as herein shown and described.

85,842. BELT. LEWIS A. MYERS, Jr., Newark, N. J. Filed Feb. 10, 1902. Serial No. 95,241. Term of patent 34 years.

Claim.—The design for a belt substantially as shown and described.

85,843. PATTERN FOR DRESS-SKIRTS. HENRIETTA OTTOM, New York, N. Y. Filed Feb. 26, 1902. Serial No. 96,254. Term of patent 34 years.

Claim.—The design for a pattern for dress-skirts, as herein shown and described.

85,844. PATTERN FOR DRESS-SKIRTS. HERRING GUNDEL, New York, N. Y. Filed Feb. 26, 1902. Serial No. 95,836. Term of patent 34 years.

Claim.—The design for a pattern for dress-skirts, as herein shown and described.

85,845. PATTERN FOR DRESS-SKIRTS. HERRING GUNDEL, New York, N. Y. Filed Feb. 26, 1902. Serial No. 95,838. Term of patent 34 years.

Claim.—The design for a pattern for dress-skirts, as herein shown and described.

85,846. PATTERN FOR DRESS-SKIRTS. HERRING GUNDEL, New York, N. Y. Filed Feb. 26, 1902. Serial No. 95,837. Term of patent 34 years.

Claim.—The design for a pattern for dress-skirts, as herein shown and described.

85,847. PATTERN FOR DRESS-SKIRTS. HERRING GUNDEL, New York, N. Y. Filed Feb. 26, 1902. Serial No. 95,839. Term of patent 34 years.

Claim.—The design for a pattern for dress-skirts, as herein shown and described.

85,848. PATTERN FOR DRESS-SKIRTS. HERRING GUNDEL, New York, N. Y. Filed Feb. 26, 1902. Serial No. 95,839. Term of patent 34 years.

Claim.—The design for a pattern for dress-skirts, as herein shown and described.

85,849. CLOAK. HERMAN HAYES, New York, N. Y. Filed Jan. 17, 1902. Serial No. 95,834. Term of patent 34 years.

Claim.—The design for a cloak, substantially as herein shown and described.

TRADE-MARKS

REGISTERED APRIL 1, 1902.

87,996. JEWELRY. FRANK PERLA, New York, N. Y. Filed Feb. 24, 1902.

EL PERFECTO

Essential feature.—The words "EL PERFECTO." Used since October, 1898.

87,997. WRITING-PAPER. JAMES WILSON CO., Dallas, Texas. Filed Feb. 2, 1902.

Defiance

Essential feature.—The word "DEFIANCE." Used since 1872.

87,998. SHIRT-NECK. BOWLEY, HAVILAND & DUNN, New York, N. Y. Filed Jan. 2, 1902.

DU BARRY

Essential feature.—The words "DU BARRY." Used since December 15, 1901.

87,999. WEEKLY PERIODICAL. FRANK LAMMA, New York, N. Y. Filed Feb. 14, 1902.

Exchange and Mart

Essential feature.—The words "EXCHANGE AND MART." Used since January 15, 1902.

88,000. HEADGEAR. GUN & CO., London, England. Filed Jan. 4, 1902.

88,000.

Essential feature.—A shield at the top of which are certain ornamentations, on either side of the shield a rampant lion, and immediately above the shield a helmet. Used since 1893.

88,001. SUSPENDERS. CANTON Suspenders Co., Boston, Mass. Filed Sept. 18, 1901.

EVERLASTIC

Essential feature.—The word "EVERLASTIC." Used since July 22, 1900.

88,002. CORSETS. KIM BROS., New York, N. Y. Filed Feb. 12, 1902.

NU-RAY

Essential feature.—The hyphenated word "NU-RAY." Used since February 1, 1902.

88,003. CORSETS. SYDNEY, ADAMS & CO., New Haven, Conn. Filed Feb. 4, 1902.

C/B ALA SPIRITE

Essential feature.—The letters, diagonal line, and words "C/B ALA SPIRITE." Used since January 1, 1900.

88,004. COLLARS AND CUFFS. UNION COLLAR COMPANY, Troy, N. Y. Filed Dec. 6, 1901.

Essential feature.—The representation of a situation. Used since October 16, 1901.

88,005. COLLARS AND CUFFS. UNION COLLAR COMPANY, Troy, N. Y. Filed Dec. 6, 1901.

Label

Essential feature.—The word "LABOR." Used since October 16, 1901.

88,006. **HOINKRY.** PHILLIPS & MARBLEY, Philadelphia, Pa. Filed Nov. 20, 1901.

Essential feature.—The representation of a battle-ship or cruiser and the word "OLYMPIA." Used since June, 1899.

88,007. **BOOTS AND SHOES.** FRANK & DUNTON, Marlboro, Mass. Filed Jan. 28, 1902.

Essential feature.—The words "OLD PUT," associated with the portrait of General Israel Putnam. Used since May 1, 1901.

88,008. **BOOTS AND SHOES.** FERRIS SHOE COMPANY, St. Louis, Mo. Filed Mar. 2, 1902.

Academy.

Essential feature.—The word "ACADEMY." Used since March 1, 1901.

88,009. **SHOES.** TOWN & HARRIS, West Winfield, N. Y. Filed Dec. 20, 1901.

College

Essential feature.—The word "COLLEGE." Used since October 20, 1901.

88,010. **BORSE-BLANKETS.** WILLIAM AYER & SONS, Philadelphia, Pa. Filed Feb. 25, 1902.

NOTAIRE

Essential feature.—The word "NOTAIRE." Used since January 1, 1902.

88,011. **COTTON FABRICS.** WARR, HANNEY & CO., London, England. Filed Mar. 4, 1902.

Essential feature.—The representation of a running stag. Used since March, 1875.

88,012. **WOOL WARDING.** NORMAN & EVANS, Lockport, N. Y. Filed Oct. 24, 1901.

Golden Fleece

Essential feature.—The words "GOLDEN FLEECE" and the representation of a tablet with four extended wings, the capital letters "H" and "E" on said wings, and a picture of a lamb's head arranged on said tablet. Used since April 1, 1896.

88,013. **TABLETS OR PELLETS FOR THE TREATMENT OF THE BRONCHITIS.** ROBERT ADAM BRADSHAW, Chicago, Ill. Filed Feb. 24, 1902.

NIX-E

Essential feature.—The hyphenated word "NIX-E." Used since February 2, 1902.

88,014. **STUPE, PICTURES, FILLS, PLASTERS, OINTMENTS, SOAPS, AND PERFUMES.** SUGGS & WHITE, Boston, Mass. Filed Feb. 2, 1902.

SANDERNA

Essential feature.—The word "SANDERNA." Used since January 25, 1902.

88,015. **PERFUMES.** ARON & LE FEVRE, Lancaster, Pa. Filed Aug. 8, 1901.

ACTON

Essential feature.—The word "ACTON." Used since September 1, 1900.

88,025. CERTAIN NAMED DRUGS. THE L. RICHARDSON DRUG Co., Greenboro, N. C. Filed Jan. 22, 1902.

Essential feature.—A triangular frame including a field in which is arranged a group of faces representing persons of different ages. Used since April 1, 1900.

88,026. STOMACH-BITTERS. BATES BROS. LADDER & CHAS. CO., Ltd., Baton Rouge, La. Filed Feb. 21, 1902.

ISTROUMA

Essential feature.—The word "ISTROUMA." Used since June, 1887.

88,027. MEDICINAL TABLETS. CLARK & CO., Baltimore, Md. Filed Feb. 14, 1902.

ENERJETS

Essential feature.—The word "ENERJETS." Used since January 15, 1902.

88,028. MEDICINAL TABLETS. EGYPTIAN MANUFACTURING Co., Grand Rapids, Mich. Filed Feb. 12, 1902.

CALENDAR.

Essential feature.—The word "CALENDAR." Used since February 1, 1902.

88,029. PROPRIETARY MEDICINE. THE HARBOR MEDICAL Co., Montreal, Canada. Filed Feb. 14, 1902.

HARBOR

Essential feature.—The word "HARBOR." Used since December 10, 1901.

88,030. MEDICINAL PREPARATIONS FOR ASTHMA, CATARRH, AND RAY-FEVER. THE T. & A. CHEMICAL Co., Dayton, Ohio. Filed Jan. 24, 1902.

88,080.

RECAL

Essential feature.—The word "RECAL." Used since January 1, 1901.

88,081. SPECIFIC FOR THE CURE OF KIDNEY AND BLADDER COMPLAINTS. FOSTER-McGILLAN Co., Buffalo, N. Y. Filed Feb. 12, 1902.

Essential feature.—The representation of a person holding the hands to the back. Used since January 2, 1902.

88,082. SALVE. EDWARD BENTON, Waco, Tex. Filed Feb. 12, 1902.

Essential feature.—A five-pointed star having a picture of registrant's head and neck therein, a circle surrounding the star, and an inner circle broken by the star. Used since January 1, 1900.

88,083. WINE. CAMEL WINE Co., New York, N. Y. Filed Feb. 25, 1902.

CAMEL

Essential feature.—The word "CAMEL." Used since November, 1900.

88,084. WINE. CAMEL WINE Co., New York, N. Y. Filed Feb. 25, 1902.

REHOBOTH

Essential feature.—The word "REHOBOTH." Used since November, 1900.

88,085. MALT PREPARATIONS. LOEWEL HAY, Hamburg, Germany. Filed Feb. 12, 1902.

MALT BEANS.

Essential feature.—The word "MALT BEANS." Used since February 1, 1902.

88,086. COFFEE AND TEA. FRANK E. WILSON, New Orleans, La. Filed Feb. 27, 1908.

DELIGHT

Essential features.—The word "DELIGHT" and the representation of an eagle's nest with the old and young birds. Used since February 11, 1908.

88,087. COFFEE, TEA, AND SPICES. SCHWENKER-SCOTTISH COFFEE COMPANY, St. Louis, Mo. Filed Feb. 24, 1908.

Ocean.

Essential features.—The word "OCEAN." Used since January 15, 1908.

88,088. WEIRAY-PLATE. H. B. FILLIS & CO., Toledo, Ohio. Filed Mar. 4, 1908.

Essential features.—The words "STELLAR KEY" and the representation of a key. Used January, 1907.

88,089. LARD AND LARD CONTAINER. ARMOUR & COMPANY, Chicago, Ill. Filed Mar. 3, 1908.

Essential features.—The words "WHITE CLOUD," associated with the representation of the head of an Indian. Used since February 1, 1908.

88,040. DEVICES FOR HOLDING SHOES WHILE CLEANING OR POLISHING THE SAME. ARTHUR J. SUMNER, Springfield, Mass. Filed Feb. 24, 1908.

DANDY-SHINER

Essential features.—The words "DANDY" and "SHINER" with a hyphen between them. Used since June 15, 1901.

88,041. PLASTER FINE. ARTHUR H. SUMNER, Boston, Cal. Filed Feb. 11, 1908.

HERCULES

Essential features.—The word "HERCULES." Used since January 1, 1900.

88,042. KIDNEY. GLOBE VENTILATOR COMPANY, Troy, N. Y. Filed Feb. 12, 1908.

GLOBE

Essential features.—The word "GLOBE." Used since December 31, 1897.

88,043. BARNETT METAL. HENRY J. BARNETT, Kansas City, Mo. Filed Feb. 7, 1908.

Essential features.—The letter "R" and an elliptical figure. Used since August 1, 1901.

88,044. WREN PRINCIPLE. FREDERICK A. WREN, Richmond, Ind. Filed Feb. 12, 1908.

ROYAL

Essential features.—The word "ROYAL." Used since March 1, 1899.

88,045. POINTS OF TYPE. AMERICAN TYPE FOUNDRY COMPANY, New York, N. Y. Filed Feb. 23, 1908.

Adtype

Essential features.—The word "ADTYPE." Used since January 1, 1902.

88,046. WRITING-MACHINES AND TYPE-WRITERS. THE IMPERIAL WRITING MACHINE CO'Y. (LIMITED) Montreal, Canada. Filed Feb. 26, 1902.

Empire

Essential features.—The word "THE EMPIRE." Used since December, 1894.

88,047. GAS AND CARBURET ENGINE AND MOTOR. THE WHEAT GAS AND CARBURET ENGINE COMPANY, Kansas City, Mo. Filed Feb. 15, 1902.

Essential features.—The representation of a Maltese cross. Used since December 1, 1900.

88,048. KNIVES FOR CERTAIN NAMED COMBES. THE POWERS MANUFACTURING COMPANY, Philadelphia, Pa. Filed May 12, 1902.

San to lin

Essential features.—The word "SANTOLIN." Used since November, 1897.

88,049. PUBLICATIONS, PERIODICALS, MAGAZINES, AND BOOKS. H. CHAMBERLAIN, New York, N. Y. Filed Feb. 4, 1902.

NEW ERA

Essential features.—The representation of the sun, photographs, and the words "NEW ERA." Used since June, 1901.

DECISIONS

OF THE
COMMISSIONER OF PATENTS
AND OF
UNITED STATES COURTS IN PATENT CASES.

COMMISSIONER'S DECISIONS.

EX PARTE GIBON.

Decided March 5, 1902.

1. INOPERATIVENESS—AEROPLANE—FAILURE OF EXAMINER TO STATE REASONS.

Where an Examiner rejects claims for an aeroplane on the ground of inoperativeness upon the allegation that there is no instance in the history of the art of a successful ascent and prolonged flight without the aid of a gas-field, Held that he has not complied with the rule which requires him to state his reasons for rejection.

2. SAME—FAILURE OF OTHERS TO ACCOMPLISH RESULT.

This Office was created and exists for the sole purpose of encouraging inventors to furnish means to accomplish results which have not before been accomplished, and therefore it cannot consistently refuse a patent upon the sole ground that no one has heretofore succeeded in accomplishing the result had in view.

3. SAME—INOPERATIVENESS DUE TO DEFECTS—DEFECTS SHOULD BE POINTED OUT.

If a device is inoperative, it is because of some defect in principle or mechanical construction and not because similar devices have not been made operative, and the Examiner should point out the real reasons why he regards the device as inoperative.

4. SAME—OBJECTION OF INOPERATIVENESS NOT WELCOME—SHOULD NOT BE MADE DOGMATICALLY.

As a matter of practice this Office should not arbitrarily place upon the applicant the burden of proving that the device is operative without stating the reasons why it is regarded as inoperative, since the objection of inoperativeness is not a welcome one and should not be made dogmatically.

ON petition.

AEROPLANE.

Application of Theodore Gibon filed April 24, 1901, No. 57,229.

Messrs. Howson & Howson for the applicant.

ALLEN, Commissioner:

This is a petition asking that—

the Examiner be instructed to withdraw his demand for a demonstration of the practical operativeness of the device and also to withdraw his demand for further drawings.

The invention in this case is an aeroplane, and the Examiner takes the position that the device disclosed is inoperative, saying:

There is no instance in the history of the art of a successful ascent and prolonged flight without the aid of a gas-field. Aside from any other consideration, no claims based upon the present device can be allowed until its operativeness is demonstrated. The most satisfactory means of doing this is a model.

The applicant cites certain publications as showing that successful flight without a gas-field is possible and has been accomplished. The real question in this case, however, is not whether any one has ever accomplished successful flight with an

aeroplane, but whether the device in this case is operative and useful for the purpose for which it is intended. If it is operative, it is not of consequence whether any operative devices upon similar lines have heretofore been made. It is the very purpose of invention to do that which had not been done before, and this Office cannot consistently allege as a reason for refusing a patent the mere fact that no one heretofore has succeeded in accomplishing the result had in view. This Office was created and exists for the sole purpose of encouraging inventors to furnish means to accomplish results which have not before been accomplished.

If this applicant's aeroplane is inoperative, it is because of some defect in principle or in mechanical construction and not because no one has been able to make similar devices operative. If the Examiner is of the opinion that this device is inoperative, as he appears to be, it is undoubtedly his duty to reject the claims, as was done in this case, and that action is reviewable in the first instance by the Examiners-in-Chief upon appeal. As a matter of practice, however, this Office cannot properly in a case of this kind arbitrarily place upon the applicant the burden of proving that the device is operative without stating the reasons why it is regarded as inoperative. The assertion of inoperativeness is not a welcome objection and should be made only when supported by a statement of the reasons therefor and not dogmatically. The applicant obviously cannot know what argument to make in his efforts to convince the Examiner until he knows what position the Examiner takes. As has been frequently stated, it is necessary to the proper prosecution of an application that the applicant and the Examiner understand each other's position in the case.

The drawing in this case illustrating the entire machine necessarily shows the parts upon a small scale. The illustration in Figure 2 of the pipes and valves is sufficient to enable one skilled in the art to understand the invention, and it is thought that an additional view showing them upon a larger scale is not only unnecessary, but would not materially assist an understanding of the invention.

No necessity is seen for illustrating the door by which the engineer enters the machine. It is not claimed, and in so far as this invention is concerned it is not of consequence how the engineer enters the machine. The applicant expresses a willing-

ness to further illustrate the shell for the engineer. That is the only requirement for additional illustration which should be insisted upon.

To the extent indicated the petition is granted.

DUDLEY C. BLICKENSCHER AND BARNES V. SEDGWICK.

Decided March 5, 1902.

1. INTERFERENCE—MOTION TO REOPEN—NEWLY-DISCOVERED EVIDENCE—DILIGENCE.

Where an interference is reopened to permit the taking of the testimony of a single witness and after the case is again closed a motion is made to take the testimony of other witnesses to corroborate him, *Held* that the motion should be denied in the absence of a showing that the testimony could not have been produced by the exercise of diligence.

2. NEW TRIAL—NEWLY-DISCOVERED EVIDENCE—REASONABLE DILIGENCE.

A new trial will not be granted on the ground of newly-discovered evidence where that evidence could have been discovered before trial by the exercise of reasonable diligence.

APPEAL ON MOTION.

TYPE-WRITING MACHINE.

Application of George W. Dudley filed October 17, 1899, No. 733,889. Application of George C. Blickenscher and William O. Barnes filed November 26, 1898, No. 697,532. Application of Frederick Sedgwick filed September 2, 1898, No. 690,200.

Mr. Ellis Spear for Dudley.

Mr. William Cranch McIntire for Blickenscher and Barnes.

Mr. David H. Fletcher and Mr. L. S. Bacon for Sedgwick.

ALLEN, Commissioner:

This is an appeal from the decision of the Examiner of Interferences denying a motion brought by Blickenscher and Barnes to reopen the above-entitled interference with permission to take newly-discovered evidence in corroboration of the witness Stevens Rogers's testimony in rebuttal.

It appears from the record that after testimony had been filed the interference was reopened and permission was granted to Blickenscher and Barnes to take the deposition of Rogers, who had previously testified in the case in behalf of Sedgwick. This permission was granted in view of certain affidavits, among them one by Rogers to the effect that he had been mistaken in testifying in behalf of Sedgwick; that he (Rogers) had gone into Sedgwick's employ about the first of October, 1897, and had assisted in building a type-writing machine which was completed about the 8th, 10th, or 12th of December, 1897; that he had been led to so testify from a memorandum of dates furnished to him by Frederick Sedgwick; that upon further investigation he was satisfied that he had not gone to work at the time stated, but that, on the contrary, he did not go into the employ of Sedgwick until sometime in the month of April or May, 1898. It appears, further, that Rogers's misconception of the dates as testified to by him was due to the fact that he could not find his time-book before he testified, but that he afterward found this time-book and discovered that he did not go into the employ of Sedgwick until April or May, 1898.

In an affidavit in support of the present motion attorney for Blickenscher and Barnes states—that during the examination of said Rogers's memoranda of dates and circumstances and a time-book were produced by said Rogers and put in evidence and duly marked as exhibits in rebuttal, all tending to prove and, as dependent then and now believes, proving the statements testified to by said Rogers in rebuttal; that, confidently relying upon said testimony and exhibits, and being circumscribed by the decision of the Acting Examiner of Interferences, to the production of Stevens Rogers only as a witness, and having at such time no knowledge of any other corroborating witness or state of facts, no other witness was produced in rebuttal.

From the above statement it is clear that at the time the witness Rogers testified in rebuttal it was believed that his testimony, together with the exhibits introduced therewith, would be sufficient to establish the fact that he was not in Sedgwick's employ in October and December, 1897. It was not considered necessary to produce evidence to show where he was at this time, and it does not appear that any effort was made to do so. If such evidence were considered necessary to corroborate Rogers's statements, then was the time to produce it. The attorney for Blickenscher and Barnes in his affidavit states, however, that he—

took pains to satisfy himself as to the truthfulness of the statements made to him and testified to in rebuttal by the said Rogers, and became satisfied that said Rogers's statements were truthful in every respect, and worthy of belief, and deponent therefore relied upon the deposition as sufficient.

Clearly there is no showing that the evidence now sought to be introduced could not with diligence have been discovered at the same time that Rogers's mistake in his first testimony was discovered. Hence it is not such newly-discovered evidence as would warrant a reopening of the case at this late day. The authorities are unanimous that a new trial will not be granted on the ground of newly-discovered evidence which could have been discovered before trial by the exercise of reasonable diligence. (*Encyclopedia of Pleading and Practice*, Vol. 14, p. 799.) The present case, however, was reopened once to permit the introduction of testimony of the nature of that now sought to be introduced, and it was the duty of appellant to exercise diligence at that time to produce all the evidence then obtainable.

There is no error in the decision of the Examiner of Interferences, and it is accordingly affirmed.

EX PARTE CROWLEY.

Decided March 15, 1902.

1. TRADE-MARK—REGISTRATION MUST AGREE WITH MARK AS USED.

The law is very clear that the mark which is shown and described in the registration must be the same as the mark which is actually used. There is no provision for the registration of a mark not in actual use or which differs from that in actual use. (*Citing ex parte Hall*, 98 O. G., 3174.)

2. SAME—INVARIABILITY.

There is no provision in the law for registration of a mark which may be varied as circumstances may render it necessary or desirable. To use such a variable mark would defeat the very purpose for which a trade-mark is intended.

3. SAME—VARIANCE BETWEEN SHOWING AND STATEMENT OF USE.

When the facsimile shows the mark as comprising the word "Tunnel," together with certain pictorial representations, and it is stated that the word "Tunnel" alone may be used, *Held* that registration should be refused.

4. SAME—LIMITATION OF SHOWING AND DESCRIPTION.

Held, further, that if the registration is intended to cover the word "Tunnel" alone the pictorial representation should be erased from the drawing and the description thereof canceled. If, on the contrary, it is intended to cover the mark as it is shown in the facsimile, the statement of essential features and the description should be made to conform to such showing.

ON appeal.

TRADE-MARK FOR FOOTWEAR.

Application of Thomas Crowley filed January 12, 1902, No. 64,842.

Mr. James L. Norris for the applicant.

ALLEN, Commissioner:

This is an appeal from the action of the Examiner of Trade-Marks requiring that certain pictorial representations shown in the facsimile be included in the statement of the essential features of the mark for which registration is sought.

Applicant states that his trade-mark consists of the arbitrarily-selected word "Tunnel," and further states that the essential feature of the mark is the arbitrarily-selected word "Tunnel."

The facsimile of the mark disclosed in the drawing shows that this mark is used in connection with the pictorial representation of a miner's cap, lamp, and tools.

Applicant states that the mark is generally arranged as shown—that is, the word together with the pictorial representation—but that the pictorial representation may be omitted and other matter used in connection with the word.

The law is very clear that the mark which is shown and described in the registration must be the same as the mark which is actually used. There is no provision for the registration of a mark not in actual use or which differs from that in actual use. (*Ex parte Hall*, 98 O. G., 3174.)

Applicant states in his application that the mark is used as shown—that is, with the pictorial representation—or that it may be used without such pictorial representation—that is, it may consist solely of the word "Tunnel."

The word "Tunnel" to the eye clearly differs from the same word used in connection with the pictorial representation. In the mark shown this pictorial representation appeals to the eye, and it cannot be maintained that such representation is not an essential feature of the mark when its appearance alone is considered.

It is evidently applicant's desire to cover by the registration now sought a mark which may be varied as circumstances may render it necessary or desirable. There is no provision in the law, however, for such a registration. The mark as described is devoid of those indicia which must be borne by the symbols known to commerce and jurisprudence as trade-marks. Such symbols must have invariability. They must be fixed, positive, unmistakable. (*See Brooks on Trade-Marks*, sec. 142.) The reason for this requirement is that the public may not be deceived or misled. In the present case if the word "Tunnel" alone appears on goods at one time and the same word with the pictorial representation at another time purchasers would be in

[Vol. 90,

doubt as to the origin of the goods. They could not know whether or not such goods were the product of the same maker. To use such a variable mark would therefore defeat the very purpose for which a trade-mark is intended. There is no provision in the law for the registration of such a mark. (*Ex parte Hall*, *supra*.)

It is clear, therefore, that if this registration is intended to cover the word "Tunnel" alone the pictorial representation should be erased from the drawing and the description thereof canceled. If, on the contrary, it is intended to cover the mark as it is shown in the facsimile, the statement of essential features and the description should be made to conform to such showing.

The decision of the Examiner of Trade-Marks is affirmed.

DECISIONS OF THE U. S. COURTS.

Supreme Court of the United States.

BUSCH V. JONES *et al.*

Decided March 17, 1902.

1. PATENTS—JONES—PROCESS OF DRY-PRESSING—FUNCTION OF MACHINE.

Claim 5 of Letters Patent No. 204,741, granted to Joshua W. Jones, for a process of dry-pressing and removing type indentations from printed sheets *Held* invalid, as covering merely the function of the machine. (Decision below, 16 D. C. App., 22, reversed.)

2. PROCESS—DRY-PRESSING—OPERATION OR EFFECT OF MACHINE—CLAIM INVALID.

A claim for a process of dry-pressing which includes subjecting a collection of sheets of paper to pressure without the use of faller-boards, tying them into a bundle while under pressure, removing them from the press, and allowing them to remain tied until fixed, *Held* to describe merely the operation and effect of the machine and to be invalid.

3. ANTI-COUNTERFEITING—BOOKBINDER'S DRY-PRESS—CLAIM VALID.

Claims 1, 2, 3, and 4 of Patent No. 204,741 for a bookbinder's dry-press and sheet-tie *Held* valid notwithstanding the existence of devices of the same general character used in various arts for compressing and tying various materials.

4. INFRINGEMENT—ACCOUNTING BASED ON INVALID CLAIM—DECISION REVERSED AND CLAIM REINSTATED.

Where the lower court held all claims of the patent to be valid and infringed, but the accounting was based upon the infringement of claim 5 and that claim is found on appeal to be invalid, *Held* that the decision below must be reversed and the case remanded for proceedings in accordance with this opinion.

APPEAL from the Court of Appeals of the District of Columbia.

STATEMENT OF THE CASE.

This suit was brought by appellees against appellant for the infringement of Letters Patent No. 204,741, and Letters Patent No. 452,893, issued to Joshua W. Jones, one of the appellees. An accounting was prayed, and also an injunction, pending the suit. The bill contained the usual allegations of invention and utility, and of infringement by the defendant (appellant). The answer traversed those allegations, and alleged prior use, disclosure of the invention in prior publications, and also anticipation by prior devices and processes. The answer contained a list of the devices. No evidence was given as to, and no judgment passed on, Patent No. 452,893. This appeal therefore is only concerned with Patent No. 204,741. The pat-

No. 1.]

ent was issued to Joshua W. Jones, one of the appellees, for a press and process (the relation of the two is disputed) for "dry-pressing" and removing type indentations from printed sheets. The validity of the patent was sustained, and its infringement by the defendant (appellant) was found by the Supreme Court of the District of Columbia, and decree passed adjudging appellees the sum of \$3,491.70 with interest and costs. The decree was affirmed by the court of appeals. (16 D. C. App., 28.) The case was then brought here. The facts are stated in the opinion.

Mr. George J. Murray for the appellant.

Mr. M. W. Jacobs for the appellee.

Mr. Justice McKENNA delivered the opinion of the Court.

1. A question of jurisdiction is raised. It is contended by appellant that the case was not one of equitable cognizance, the appellees' remedy being, it is claimed, at law. The specification of error upon which the contention is based is expressed as follows:

Because at the time of the hearing it appeared from the record that the only patent before the court had expired before the hearing, no motion for preliminary injunction having been made prior to the expiration of the patent, and defendant being a mere user of one machine, which machine was destroyed by fire before the case was brought to hearing.

This seeks to determine the jurisdiction of the court by conditions which came into existence after the commencement of the suit, not upon those which existed at the time the bill was filed. It is, however, urged in argument that the contract between Jones and the W. O. Hickok Manufacturing Company conveyed the patent-rights to the press only, and not the process described in the fifth claim of the patent, and that "the court, sitting as a court of equity, had no jurisdiction to order an injunction at the time the bill of complaint was filed." But what the contract provided was an issue to be made in the case, and pending its decision the preliminary relief by injunction could have been granted. Appellees' contention as to the jurisdiction is, therefore, not justified, and a discussion of the reasons for this conclusion is not necessary. They are expressed in *Clark v. Wooster* (37 O. G., 1477; 119 U. S., 323) and *Beidle v. Bennett*, (39 O. G., 297; 123 U. S., 71.)

2. The patent is designated an "Improvement in bookbinder's dry-press and sheet-tie." That is, a new press and process for removing type indentations from printed papers or sheets, the latter when folded being designated technically as "signatures."

The type indentations are made in printing, the type displacing somewhat the fiber of the paper, and the removal of the indentations is technically known in the art as "dry-pressing," and the device by which it is done is called a "dry-press." Such a press the patent is intended to cover, and also a particular process for dry-pressing. As a process the validity of the patent is questioned, as a new machine its invention is controverted. An inquiry into the prior art becomes therefore important, and a witness, describing it and its imperfections, testified as follows:

Previous to the invention of Mr. Jones as described in said patent, it was the custom to press printed sheets by inserting them

between heavy paper boards, sometimes called "fuller-boards," but generally now called "glassed boards," and putting said boards with the printed papers between them into a powerful press, by which pressure was produced on said boards by various means, sometimes by means of screw-pressure, sometimes by hydraulic pressure. After the pressure was produced on the paper it was continued by allowing the press to remain with its pressure on to its fullest extent for ten or twelve hours or more, say from one night to the next morning, when the pressure was removed, the papers and boards taken from the press and separated by removing the boards from the pile of combined boards and paper, and putting the boards on one side on one pile and making another pile of the printed papers. This was necessarily comparatively a slow process, inasmuch as with one press only as much printed paper as the press would hold when put between the boards could be pressed in about ten or twelve hours, so that where much work had to be done a number of such presses were necessary. It was also costly as to labor, because the sheets had to be placed between the boards and removed therefrom afterward, which took much time, especially where, as in the case of fine work, only one sheet was placed between two boards; and when this was done comparatively few sheets could be pressed at once because the boards took up much more room than the paper did, they being quite thick.

It was to meet this condition that the Jones patent was conceived, and its object is stated to be first to "furnish a bulk-compressor device, to be used to prepare the matter properly before it is inserted in the dry-press proper, thus saving time or repeated travel by the latter, before the operation of tying; second, to furnish a dry-press proper in which the compressing parts or heads—that is, the base and plunger—are constructed dividually, or with ways through them, to afford access through them, to readily insert and manipulate the twine, and to tie the bundles of paper while held compressed, thus securing the bundle together by a powerful tie, which, when they are removed from the press, retains its force *ad libitum*; third, a press-frame, having sides peculiarly set and arranged, and provided with longitudinal slots therein corresponding with the ways in the press-heads, above referred to, and for the same purpose, as well as to rightly lodge and center the paper with relation to the middle of the press-heads; fourth, certain ledges in the said press-frame and guides on the plunger thereof, to properly center different-sized sheets in press to secure the tie at the middle of the bundles both ways; fifth, a new process for treating printed and folded sheets of paper in dry-pressing, consisting of subjecting a collection of such sheets to pressure without the use of fuller-boards, and while under such pressure tying them into compact bundles, with end boards thereon; then removing them immediately from the press, and allowing them to remain tied sufficiently long to fix and complete the dry-pressing."

The press is described in the patent with particularity, and illustrated by drawings. It may be said, generally, that it is a press in which bundles of signatures (sheets) are placed, at the end of which bundles rigid boards are attached to distribute the pressure which is exerted by the press. The press moves in a "trough-formed" bed so mounted as to incline laterally "so that the folded paper may securely lodge and carry therein while being operated on." Rectangular blocks are rigidly secured at both ends of the bed. The lower block is the base of what is called in the specifications a "divided head," constructed with "openings or ways." Opposing this there is a "plunger or follower," to which there is also attached a "divided head" having "openings and ways" be-

[Vol. 99,

No. 1.]

tween the parts of the head. The "openings and ways" are to enable the operator to pass his hand between the parts of the press and tie the bundles. The operation of the press is as follows: A bundle of signatures (sheets) with rigid boards at its ends are placed in the press, pressure is exerted by means of a screw (other means may be used) which passes through the upper block and operates on the plunger or follower and the "divided head" attached to it, and as the bundle rests on the lower block and its "divided head," it is evident that the pressure on the sheets will be in proportion to the power applied. While under pressure in the press the bundles are tied, access to them being had through the openings in the "divided head." The bundle is then removed from the press and allowed "to remain tied sufficiently long to fix and complete the dry-pressing."

The advantage of the new method is that it is not so dilatory as the old and is more economical. In the old method the sheets, coming damp from the printing-press, had to be dried before dry-pressing, and had also to be subjected to pressure in the press a number of hours to effect the smoothing (dry-pressing) of the sheets. The quantity of the work, therefore, was limited by the number of presses. In other words, as expressed by one of the witnesses, "where much work had to be done a number of such presses were necessary." And it was further testified that "it (the old method) was also costly as to labor, because the sheets had to be placed between the boards (fuller-boards) and removed therefrom afterward, which took much time, especially where, as in the case of fine work, only one sheet was placed between two boards, and when this was done comparatively few sheets could be pressed at once, because the boards took up much more room than the paper did, they being quite thick." In the new method there is no such limitations as to time, nor does it require the same expenditure of money. In the new method the initial pressure is applied in the press—the subsequent pressure necessary to remove the type indentations is continued in the tied-up bundle. The operation, therefore, is comparatively rapid. "Putting the paper in the bundle," a witness testified, "tying it up in a bundle and removing it therefrom," takes a few minutes. And the longer the sheets remain in the bundles the better the effect. Some time is necessary. Another advantage is claimed. It was testified that in the Jones method that the sheets when folded have the convex impression of one half of the sheet brought in contact with the convex side of the other half of the sheet or of the sheet next to it, "and these convex impressions coming in contact with each other tend, when under pressure, to efface each other."

There is, however, no revelation in the specifications of the patent of the operation of opposing "convex impressions," nor a word to indicate that Jones was conscious of the advantage of that assistance to the pressure upon the sheets. The discovery seems to have been made by one of the witnesses, and also seems to have been disclaimed by Jones in the following question and answer:

[Vol. 99,

No. 1.]

I-Q. 35. Throughout the testimony a good deal has been said about the advantages derived from your supposed invention from the fact of the type indentations being convex or concave, whatever that may mean. Is there anything said in the patent about that?

A. No; neither do I claim that they are produced by my process.

There is a dispute as to the character of the patent. Appellees contend that it is "a process of 'dry-pressing' or removing type indentations from printed sheets," (claim 5 of the patent.) Second. "A press of peculiar construction and adapted to the convenient carrying of this process into effect. The novel features of which press are covered by claims one to four inclusive." The appellees contend that the patent is for a machine (claims 1 to 4) and also for a process, (claim 5.) And it is asserted the latter claim is but an operation or function of the machine. It is further contended that the machine and process were anticipated.

In discussing these contentions, it is not necessary to minutely observe the distinctions made and disputed by counsel. Even if the patent is primarily for a novel process, there is a claim for a novel press, and, by the consideration of the latter, we think, the validity of the former will be determined.

Was, then, the press anticipated, including broadly in the term the inquiry whether the press exhibited invention, in view of the prior state of the art? Anticipation is a question of fact, and the burden of establishing it is on the appellant. The patent bears a presumption of novelty and invention, and the lower courts, passing on the evidence, found against appellant's contention. Such united judgment this Court accepts unless there is a clear showing to the contrary. (*Brainard et al. v. Buck et al.*) That showing appellant claims the record establishes, and even urges that presses of various kinds had become so familiar, before the Jones patent, that judicial knowledge can be invoked for them. Hay-presses, cotton-presses, tobacco, wool and other presses are instances, all of which, it is said, were used for applying pressure to masses of matter to compact them into bundles, and in all of which the pressure was retained by strings, ropes or bands of some kind. But wherein those presses differed one from the other and received special characterization and utility would be a matter of proof, not of assumption, and wherein the Jones patent differs from either of them and has derived its special applicability is certainly not so clear that it is demonstrated against the judgment of the Supreme Court and the Court of Appeals of the District. Nor are we nearer that demonstration by the specific patents, put in evidence by appellant. There is generic sameness we concede, but there are differences, and the Patent Office and both lower courts found novelty and invention in those differences.

The appellant introduced in evidence a patent issued to D. Kellogg, October 12, 1863, for a wool-press; one to W. R. Dingham, October 20, 1863, for improvement in paper-presses; one to S. Cooley, October 13, 1866, for a wool-press; to Thomas Stibbe, September 13, 1871, for pressing yarn; to W. P. Craig, for a baling-press; to Thomas G. Hardesty,

for tobacco-press; to G. B. Archer, for baling manure and other substances; to C. Brown, for baling short-cut hay, and another for baling short-cut straw; and a patent for a signature-press to R. A. Hart. There was also testimony of the existence of a press used in the bookbinding of one John Palmer, in Philadelphia. The press was used in a later stage of bookbinding than "dry-pressing," for the purpose of tying printed sheets into bundles for storing. It was an upright press with opposing platens or heads in which there were grooves to receive the cords by which the bundle was tied while under pressure.

There is a certain resemblance between all of the devices. They are all instruments for exerting pressure upon substances placed between compressing heads or followers to compact such substances into bundles and afford facilities for tying the bundles while they are under pressure. The Dingham patent, the one most relied on by appellant, may be selected for illustration.

The Dingham device is an "improvement in paper-presses," and the inventor claimed to have "invented a new and useful machine for combining and facilitating the operation of pressing and tying paper into reams or bundles," which he called "the combination paper-press and tie-engine."

There were defects in the art of pressing and tying paper very similar to the defects in the art of dry-pressing "signatures," and Dingham described the former as follows:

The process of pressing and tying paper now generally employed requires a large and somewhat expensive press, which is located in some corner of the finishing-room, and as the paper comes from the machine it is carried to the finishing-table, there counted and folded, and when sufficient is obtained to fill the press (usually about one hundred reams) it is conveyed to the press and placed thereon, and, by means of a large screw and follower, pressed for about twelve hours, or during the night. It is then removed and conveyed to the tie-table and there tied into reams. After this (it being, when it comes from the machine, usually double crown, or double the length of the ordinary ream of wrapping-paper) it is cut into two reams or single crown. The usual mode of tying paper is by passing a strong cord or twine around the ream, with a noose or loop at the end, through which the other end is passed, and then drawn upon with the hand until the loose ream or bundle is sufficiently compressed. This operation is laborious and tedious, occupying much time, requires strong twine, and unavoidably draws the ream away or the paper out of place.

This language is quite similar to that used by Jones and his witnesses to describe the defects which existed in the bookbinders' art, and the processes of the inventors also have similarity. In both sheets of paper are pressed by being placed between "compressing-heads," which "are constructed dividually," to use the words of the Jones patent, "separate and sufficiently disconnected (to use the language of the Dingham patent) to allow the string or cord for tying the paper to pass between." Each machine, therefore, comprises a compress and tie-table. In each there is the same rapidity of operation, the same economy of time and means, and in each the pressure first applied by the machine is retained by cords and continued in the bundle. And it is manifest that this retained and continued pressure, which has for its purpose in the Jones patent to remove type indentations from the sheets, and in the Dingham patent to retain the sheets in the bundle, adds nothing to the operation of the press of the former and detracts nothing from the operation of the press of the latter. But notwithstanding these reser-

blances we may ascribe invention to the Jones patent if it be confined to the press proper. In other words, the press may be regarded as a form, adapted to the bookbinders' art, and although preceded by the Dingham patent in a general way, may be considered as an invention of that form.

The fifth claim of the Jones patent—the claim for the process—must be viewed from a different standpoint. The first four claims of the patent, as we have said, describe the elements, "in a printer's and bookbinder's dry-press and sheet-tie." The fifth claim is as follows:

5. The process herein described for treating folded printed sheets of paper in dry-pressing, the same consisting of subjecting a collection of such sheets to pressure without the use of fullers-boards, and while under such pressure tying them into compact bundles with end boards, then removing them immediately from the press, and allowing them to remain tied sufficiently long to fix and complete dry-pressing.

The dependence, therefore, is not, as counsel for appellee contends, the press upon the process. It is the other way, the process upon the press; for it is impossible to consider the fifth claim as describing anything but the operation and effect of the press. Indeed, the process is the whole value, the sole purpose of the press. What, indeed, is the process—what is the force at work? And the inquiry is entirely independent of questions as to what constitutes a patentable process discussed by this Court in *Rison Locomotive Works v. Medart* (71 O. G., 701; 188 U. S., 68) and in *Westinghouse v. Boyden Power Brake Co.* (83 O. G., 1067; 170 U. S., 587.) What, then, is the force at work and how is it applied? It is force (pressure) applied to sheets of paper placed between "compressing-heads." In other words, a special application of pressure began in the press and continued in the bundle by means of strings and cords. This, however, is the operation and effect of the machine, and it is none the less so because the pressure is held indefinitely. Its existence in the bundle is not independent of the press. The pressure is as much an effect in the bundle as when first applied. The pressure is applied by the press and so, substantially, are the bands or cords which continue the pressure, and we cannot assent to the view that the continuation of the pressure in the bundles with the consequence of removing type indentations in the printed sheets is anything but the natural and direct effect of the machine.

Infringement was put in issue by the pleadings and passed on by the lower courts. They found as a fact that all the claims of the patent had been infringed by appellant. The finding is not absolutely disputed. The assignment of error is "that the patented machine used by defendant, in view of the state of the art preceding Jones's invention, did not infringe any claims of the patent in suit." That is, appellant contends that the evidence exhibits a complete anticipation, or so limits and narrows the Jones's invention as to make the differences between the Jones press and that which was used by appellant more than formal. We have decided that the Jones press had not been anticipated, and both of the lower courts have found that the differences between it and appellant's press were not substantial. The evidence sustains the finding. The witnesses on behalf of appellees testified to the differences between the presses. They pointed out the essential resemblances of the processes and the merely formal character of the differences. There was no opposing testimony.

The accounting in the lower court, however, was had upon the basis of the validity of the process, (claim 5,) and therefore the judgment of the court of appeals must be reversed and the cause remanded, with directions to that court to reverse the judgment and decree of the supreme court and remand the cause to the latter court for further proceedings, in accordance with this opinion. So ordered.

Indexes to Patents on Electricity.

Indexes to patents relating to electricity, covering the period of time from July 1, 1880, to June 30, 1901, have been issued, and are for sale. These indexes, arranged alphabetically, numerically, and by classes, comprise the following volumes, the prices of which are given below:

Vol. 1. Index to patents relating to electricity granted by the United States prior to June 30, 1881, with an appendix, July 1, 1881, to June 30, 1880. One volume, 260 pages. In paper covers, \$1.00; bound, \$2.00.

Vol. 2. Appendix No. 2, July 1, 1880, to June 30, 1881. One volume, 80 pages. In paper covers, \$1.50.

Vol. 3. Appendix No. 3, July 1, 1881, to June 30, 1882. One volume, 80 pages. In paper covers, \$1.50.

Vol. 4. Appendix No. 4, July 1, 1882, to June 30, 1883. One volume, 80 pages. In paper covers, \$1.50.

Vol. 5. Appendix No. 5, July 1, 1883, to June 30, 1884. One volume, 80 pages. In paper covers, \$1.50.

Vol. 6. Appendix No. 6, July 1, 1884, to June 30, 1885. One volume, 80 pages. In paper covers, \$1.50.

Vol. 7. Appendix No. 7, July 1, 1885, to June 30, 1886. One volume, 80 pages. In paper covers, \$1.50.

Vol. 8. Appendix No. 8, July 1, 1886, to June 30, 1887. One volume, 80 pages. In paper covers, \$1.50.

Vol. 9. Appendix No. 9, July 1, 1887, to June 30, 1888. One volume, 80 pages. In paper covers, \$1.50.

Vol. 10. Appendix No. 10, July 1, 1888, to June 30, 1889. One volume, 80 pages. In paper covers, \$1.50.

Vol. 11. Appendix No. 11, July 1, 1889, to June 30, 1890. One volume, 80 pages. In paper covers, \$1.50.

Vol. 12. Appendix No. 12, July 1, 1890, to June 30, 1891. One volume, 80 pages. In paper covers, \$1.50.

Vol. 13. Appendix No. 13, July 1, 1891, to June 30, 1892. One volume, 80 pages. In paper covers, \$1.50.

Vol. 14. Appendix No. 14, July 1, 1892, to June 30, 1893. One volume, 80 pages. In paper covers, \$1.50.

Vol. 15. Appendix No. 15, July 1, 1893, to June 30, 1894. One volume, 80 pages. In paper covers, \$1.50.

APPLICATIONS UNDER EXAMINATION.

The Official Gazette.

THE OFFICIAL GAZETTE is published every Tuesday, simultaneously with the weekly issue of patents. From January 1, 1873, (the commencement of its publication,) to June 30, 1898, it was published and bound in semi-annual volumes; since July 1, 1898, in quarterly volumes. Terms: To subscribers within the United States, Canada, and Mexico, \$6 per annum; to foreign subscribers, \$10; single copies, 10 cents; if mailed to foreign countries, 16 cents additional for postage; bound semi-annual volumes, (prior to June 30, 1898,) full sheep, \$4 per volume; bound quarterly volumes, (subsequent to July 1, 1898,) full sheep, \$2.75 per volume. Payment in advance. No subscription will be received for less than three months. All orders should be addressed to "The Commissioner of Patents, Washington, D. C."

Renewal of Forfeited Applications.

Attention is called to section 4,397, Revised Statutes, relating to the renewal of allowed applications forfeited through failure to pay the final fee within six months from the date of allowance. The law requires the petition for renewal to be signed by the inventor, discoverer, or assignee and that the same be filed in this Office within two years after the allowance of the original application. If the inventor be dead, the petition must be signed by the administrator or executor; if insane, by the guardian, conservator, or legal representative. It will not be accepted if signed by the attorney. (Form 13, page 64, Rules of Practice, should be used.)

PATENTS

GRANTED APRIL 8, 1902.

696,918. STRAIN-SUCKING GOVERNOR. JAMES R. ALPHEM, Indianapolis, Ind. Filed May 24, 1899. Serial No. 717,978. (No model.)

Claim.—1. The combination with a rotating carrier and a shifting eccentric pivoted thereto, a centrifugal governor-arm attached to said eccentric by means of which the latter is shifted, a counteracting balance-weight pivoted at a point diametrically opposite from said eccentric to said carrier, a centrifugal governor-arm attached to said counteracting balance-weight adapted to swing in opposition to the shifting of said eccentric, and means interposed between said governor-arm controlling them to move in unison.

2. The combination with a rotating carrier on eccentric and the governor-arm by which it is swung, pivotally connected to said carrier, a counteracting balance-weight and the governor-arm connected thereto, adapted to swing said weight in opposition to the shifting of said eccentric being pivotally connected to said carrier at a point diametrically opposite from pivotal point of said eccentric, a link connection between the two said governor-arms, controlling them to move in unison, and means of weight located on said governor-arm at a point forwardly and outwardly in relation to said pivotal point, that the combined action of inertia and centrifugal forces may be caused to act in the movement of the said eccentric and counteracting balance-weight.

3. The combination with a rotating carrier, an eccentric and the governor-arm by which it is swung, pivotally connected to said carrier, a counteracting balance-weight and the governor-arm connected thereto, adapted to swing said weight in opposition to the shifting of said eccentric, said weight and arm being pivotally connected to said carrier at a point diametrically opposite from pivotal point of said eccentric, a mass of weight on each governor-arm located in a forwardly and outwardly position in relation to the pivotal point of said arm whereby inertia and centrifugal forces are caused to act in combination in the oscillation of said eccentric and counteracting weight, a link connection interposed between the two governor-arms controlling them to act in unison, a spring adapted to resist the combined inertia and centrifugal forces and means for adjusting said spring.

4. The combination with a rotating wheel or carrier, an eccentric and a pivot-shaft to one end of which it is secured, a weighted governor-arm secured at midway of its length to opposite end of said pivot-shaft, a counteracting balance-weight secured to one end of a second pivot-shaft, said pivot-shaft being mounted at points equidistant from center of rotating carrier and diametrically opposite from each other, a weighted governor-arm secured to second said pivot-shaft at opposite end from said counteracting balance-weight and in the same position in relation to rotation of said carrier as former said governor-arm and second flexure at midway of its length to respective pivot-shafts, weights located at a point outside of a tangential line in relation to the rotation of pivotal points on said governor-arms, that a combined effect of inertia and centrifugal forces result in action and links connecting to the weighted end of each said governor-arm the lever end of the other controlling them to move in unison.

5. The combination with a rotating wheel or carrier, an eccentric and a governor-arm attached at center of length to said eccentric, both mounted at a common pivotal point eccentrically in said carrier, an eccentric counteracting balance-weight and a second governor-arm attached at center of its length to said weight, and both likewise mounted at a common pivotal point diametrically opposite from pivotal point of said eccentric and equidistant from center, in said carrier, weights mounted on forward ends of said governor-arms and located outside of a tangential line drawn from the pivotal points of said arms so that the combined effect of inertia and centrifugal forces are called into action at slightest variations of speed, links interposed between said governor-arms connecting the lever end of each arm to the head or weighted end of the other arm controlling said arms to move in unison, and a spring exerting centripetal force tending to counteract the centrifugal force exerted by the combined oscillating mechanism as set forth.

6. The combination with a rotating carrier or wheel, an eccentric and a governor-arm attached at midway of its length to said eccentric, and pivoted with the eccentric at a point outside of center of the axis of said carrier, an eccentric counteracting balance-weight and a governor-arm attached midway of its length thereto, and pivoted with said balance-weight at a diametrically opposite and equidistant point from center of the axis of said carrier and from former said governor-arm and eccentric, the weighted end of said governor-arm projecting forward in relation to rotation of said carrier, links pivotally connected between said governor-arms connecting the lever end of each arm to the head or forward end of the other, and the eccentric and balance-weight being equal and playing in opposite directions over the axis of the carrier, the mechanism is most completely balanced as to gravity or running balance, weights fixed at forward or head end of said governor-arms at a point outside of a tangential line through said pivotal points, so that inertia and centrifugal forces act in combination, and a spring adapted to exert centripetal force against the combined inertia and centrifugal forces, and means for adjusting said spring, one end of said spring preferably being attached to one of said governor-arms, and the other anchored as in this case at or near a peripheral point in said wheel at an angle giving the greatest effect; all parts being equal and paired in opposition as to effect of gravity, as to produce perfect equilibrium, either in or out of action.

696,919. OIL-FILTERING AND LUBRICATING APPARATUS. JAMES R. ALPHEM, Indianapolis, Ind. Filed May 24, 1899. Serial No. 717,980. (No model.)

Claim.—1. In combination with a steam-engine, an open filtering collecting and separating box, eccentric mounted above said filtering-box that the drip or waste of lubricating-oil therefrom will drip into said box, a distributing-head and means for conducting oil from said box to said distributing-head as set forth.

2. In combination with a steam-engine a collecting filtering and separating box, eccentric mounted above said filtering-box that the drip or waste of lubricating-oil therefrom will drip into said box, a distributing-head and means for conducting oil from said box to said distributing-head as set forth.

rating box, eccentric mounted and operating above said filtering-box that the drip or waste of lubricating-oil from said eccentric will drip into said box, a distributing-basin, means for conducting oil from said filtering-box to said distributing-basin, a collecting-reservoir adapted to collect the waste or drip of oil from the working parts of the engine and means for conducting the oil thereby collected to the said filtering and separating box, whereby it is purified, filtered and cooled preparatory to being delivered to the distributing-basin for redistribution, as set forth.

3. In combination with a steam-engine a collecting, filtering and separating box, a collecting-reservoir located within the crank-case at a higher level than said filtering-box, that oil may flow by gravity to said box and adapted to collect the drip or waste oil from the operating parts of the engine, a distributing-basin located at a lower level than said filtering-box that oil will flow by force of gravity to said basin, means for distributing the oil from said basin and eccentric mounted over said filtering-box that waste oil will flow or drip from said eccentric into said box, as set forth.

4. In a steam-engine having an inclined crank-case, a reservoir or distributing-chamber at the bottom of said crank-case and a collecting-reservoir at a higher level and within said crank-case, a collecting, filtering and purifying box located outside of the engine-bed or crank-case and at a lower level than the collecting-reservoir and at a higher level than the distributing-chamber, and means for conducting the oil from the higher reservoir through the filtering-box to the lower reservoir or distributing-chamber, said filtering-box being located directly under the eccentric.

5. In combination with a steam-engine, a filtering, purifying and separating box, a collecting-reservoir, placed at a higher level than said filtering-box, that the waste oil collected by said reservoir will flow by gravity into said filtering-box to be refiltered, a distributing-basin at a lower level than the oil-discharge from said filtering-box and a separating-trap for separating and discharging the water of condensation that may accumulate in the bottom of said box; substantially as set forth.

6. In combination with a steam-engine a collecting, filtering and separating box, having screens arranged and adapted to receive and hold a filtering material and an adjustable tube having an opening or outlet below the top of said box, said tube passing down through the screen and provided with means for vertically adjusting said tube for the purpose of retaining the oil at a certain height, as specified.

696,920. PISTON GUIDING AND PACKING DEVICE. JAMES B. ALPHEE, Indianapolis, Ind. Filed May 24, 1900. Serial No. 717,061. (No model.)

Claim.—1. In combination with a steam-engine a chambered cylinder-head or distance-piece, a packing-chamber at one end of said chambered cylinder-head, an internally-threaded portion at the other end and an externally-curve-threaded sleeve adapted to be carried in threaded portion of said cylinder-head and means whereby said sleeve may be rotated for the purpose of longitudinal adjustment, as set forth.

2. In a steam-engine the combination with a chambered cylinder-head or distance-piece, an elongated guiding and packing sleeve, a lining of suitable bearing metal within said sleeve a piston-rod adapted to reciprocate within said guiding-sleeve and bearing upon said lining of bearing metal and a number of small annular grooves in the inner bearing-surface of said lining whereby condensation or lubrication may be retained, all as set forth.

3. In a steam-engine, the combination with a chambered cylinder-head or distance-piece, openings in the sides of the walls thereof for the purpose of admitting a circulation of air and means for attaching radial flanges projecting from its cylindrical portion for purposes of its attachment to bed-plate at one end and that of the cylinder thereto at the other end, a packing-chamber at the cylinder end of said head and means for the adjustment of packing within said packing-chamber, as set forth.

4. In a steam-engine the combination with a long relative guiding and packing sleeve, a concave or inwardly-flaring end surface at inner end of said sleeve, a series of compressible packing-rings reversely flared and equally on both sides being bowed outwardly toward the periphery, a series of non-compressible rings flared, or bowed toward the center line

said sleeve being preferably of larger bore than piston-rod to be packed, latter said rings being placed in packing-chamber in alternative with said compressible packing-rings, and means whereby said guiding and packing sleeve may be caused to impinge upon or against the combined body of said rings, as shown.

5. In a steam-engine the combination with a long sleeve having its outer end externally threaded and its internal surface fitted with small grooves and its walls perforated; of a compressible packing adapted to be compressed by said sleeve.

6. In a steam-engine the combination with a chambered cylinder-head, or distance-piece, an elongated packing-sleeve lined with a bearing metal, and a number of small annular grooves in inner surface thereof, as set forth.

696,931. REVERSING MECHANISM. JAMES B. ALPHEE, Indianapolis, Ind. Filed Oct. 11, 1900. Serial No. 22,794. (No model.)

Claim.—1. In a compound cut-off and reversing mechanism for valves of steam-engines, a reversing-lever and adjacently-mounted motor, whereby said lever is adapted to engage, and means for moving said motor in a longitudinal direction.

2. In a compound cut-off and reversing mechanism, a reversing-lever in combination with a longitudinally-adjustable toothed motor, said motor being carried in guides or their equivalent, an auxiliary lever or other equivalent means, for the purpose of adjustment of said motor, about the axis of its arc, and means whereby the toothed motor may be engaged temporarily with or detached to the reversing-lever.

3. In a compound cut-off and reversing mechanism, the combination with the ordinary reversing-lever, a longitudinally-adjustable motor, a rack and pinion or other suitable means for accomplishing the said longitudinal adjustment, means for temporary engagement of said motor with said reversing-lever by means of which said lever is moved upon its axis in unison with adjustment of said motor, as shown.

4. In a compound cut-off and reversing mechanism, a motor adjacently mounted in guide-ways or suitable bearings, and means by which said motor may be temporarily attached to a reversing-lever, an auxiliary adjusting-lever mounted in fixed bearings and a link or suitable connection between said movable motor and said auxiliary adjusting-lever, whereby the said motor may be moved, carrying with it at will said reversing-lever, for the purpose specified.

696,929. DISK-MAKING MACHINE. CHARLES ANDERSON, Chicago, Ill. Filed Mar. 28, 1901. Serial No. 41,670. (No model.)

Claim.—1. In a disk-making machine, the combination of the 6-male die, the pivotal male die, the staple-clamping blocks carried by said male die, and means for operating the said die.

2. In a disk-making machine, the combination of the female die, the male die on the ends of pivoted cam-levers, the staple-clamping blocks secured to said male die, the double ball-crank adapted to operate said staple mechanism and said male-die levers, and means cooperating with the driving-shaft for actuating said ball-crank.

696,932.

696,933. MACHINE FOR FORMING BARS OR SIMILAR ARTICLES. WILLIAM BARNES, Stuttgart II, Schindler, Germany. Filed July 12, 1901. Serial No. 63,071. (No model.)

Claim.—1. In a machine for forming bars or similar articles by pressing plastic metal discontinuously through dies, the press-cylinder open at both ends, two dies working in opposite directions to each other and capable of entering said press-cylinder to cut upon the plastic metal from opposite sides, and dies in said dies arranged at points between the press-cylinder and the rod of each die through which the forming articles discontinuously leave the inside of the press-cylinder.

2. In a machine of the kind described the combination of a press-cylinder with open ends and the oppositely-arranged dies provided with dies at points between the press-cylinder and the rod of each die and capable of approaching the charge in the press-cylinder discontinuously from opposite directions, substantially as shown and described.

696,934. BATTERY. WILLIAM C. BARNES, Brooklyn, N. Y. Filed Sept. 8, 1900. Serial No. 22,692. (No model.)

Claim.—1. In a battery, the combination of a liquid-holding jar, a positive element located entirely below the solution-line of said jar, a negative element, a depolarizer located partly above and partly below said solution-line, and a pair of terminals, all substantially as set forth.

2. In a battery, the combination of a liquid-holding jar, a positive element, a negative element, a pair of terminals and a depolarizer, substantially as set forth, the positive element being located entirely below the solution-line and from one-fourth to one-sixth of the body of said jar located above said solution-line.

3. In a battery the combination of a liquid-holding jar, a zinc element, a negative element, a pair of terminals and a body of acid of copper, substantially as set forth, the positive element being located entirely below the solution-line and from one-fourth to one-sixth of the body of said jar located above said solution-line.

4. In a battery, the combination of a liquid-holding jar, an oxidizing fluid, a positive element located entirely below the surface of said fluid, a negative element, a depolarizer located partly above and partly below the surface of said fluid and a pair of terminals, all substantially as set forth.

5. In a battery, the combination of a liquid-holding jar, a body of zinc, a negative element, a body of copper acid, and a pair of terminals, said zinc and copper acid being arranged in such positions relative to each

other and to the solution-line of the jar that at least one-fourth of said acid shall be a distance above the upper level of the zinc and above the solution-line, while said zinc shall be entirely below said solution-line, all substantially as set forth.

696,935. VOTING-MACHINE. ARTHUR F. BARRELL, Springfield, Mass. Assignor to Frederick Albert Barreil, Boston, Mass. Filed June 27, 1901. Serial No. 63,257. (No model.)

Claim.—1. In a voting-machine, the combination of an entrance-bar; an exit-bar; a locking device for one of said bars; and a slidable releasing mechanism which operatively connects said locking device with the other bar.

2. In a voting-machine, the combination of an entrance-bar; an exit-bar; a locking device for said entrance-bar; a locking device for said exit-bar; and releasing mechanism connecting said locking devices and operated by the opening of said bars.

3. In a voting-machine, the combination of an entrance-bar; an exit-bar; an automatic locking device by which said entrance-bar is locked when it is closed; an automatic locking device by which said exit-bar is locked when it is closed; and releasing mechanism connecting said locking devices by which one bar is unlocked by the opening of the other.

4. In a voting-machine, the combination of an entrance-bar; an exit-bar; a locking device for and carried by one of said bars; and releasing mechanism connecting said locking device and the other of said bars to release said locking device.

5. In a voting-machine, the combination of a vote-registering device; a gate-bar; a locking device for and carried by said gate-bar; mechanism

anism connected to said gate-bar and operated thereby for locking said vote-registering device; and mechanism for unlocking said gate-bar and said vote-registering device.

6. In a voting-machine, the combination of an entrance-bar; an exit-bar; a locking device for and carried by said exit-bar; a vote-registering device; locking mechanism for said vote-registering device connected to said exit-bar and operated by the opening thereof; and mechanism connected to said entrance-bar and operated by the opening thereof to release said exit-bar and said vote-registering device.

7. In a voting-machine, a plurality of registers; a register-actuator for each register; a locking-slide common to all and reciprocated by said register-actuator; an individual slide for each register-actuator, said locking-slide and said individual slide cooperating to limit the rotary movement of the register-actuator; mechanism for preventing the actuation of more than a predetermined number of registers in the group without resetting; and mechanism for resetting.

8. In a voting-machine, a plurality of registers; a register-actuator for each register; a locking-slide common to all and reciprocated by said register-actuator; an individual slide for each register-actuator, said locking-slide and said individual slide cooperating to limit the rotary movement of the register-actuator; mechanism for preventing the actuation of more than a predetermined number of registers in the group without resetting; and a resetting-strip operatively connected to said locking-slide.

9. In a voting-machine, the combination of a register; a register-actuator; a pair of slides operated by said register-actuator and seating to limit the rotary movement of said register-actuator; and a resetting-strip operatively connected with said slides.

10. In a voting-machine, the combination of a register; a register-actuator; a pair of slides seating to limit the rotary movement of said register-actuator; a resetting-strip connected to one of said slides by a lever and to the other of said slides by a stud-and-slit connection; and said lever.

11. In a voting-machine, the combination of candidate groups with a straight-tickler group; a resetting-strip for said straight-tickler group; and interlocking mechanism connecting said resetting-strip with said candidate groups.

12. In a voting-machine, the combination of candidate groups with a straight-tickler group; a resetting-strip for each of said groups; and interlocking mechanism connecting the resetting-strip of the straight-tickler group with the resetting-strips of the candidate groups.

13. In a voting-machine the combination of a plurality of registers; a plurality of register-actuators; a locking-slide common to all and reciprocated by said register-actuators; an individual slide for each register-actuator; said locking-slide and said individual slide cooperating to limit the rotary movement of the register-actuator; an independent-ballet mechanism; mechanism which prevents the actuation of a register after the actuation of said independent-ballet mechanism without resetting; and mechanism for resetting.

14. In a voting-machine, the combination of a plurality of registers; a plurality of register-actuators; a locking-slide common to all and reciprocated by said register-actuators; an individual slide for each register-actuator, said locking-slide and said individual slide cooperating to limit the rotary movement of the register-actuator; an independent-ballet mechanism; and mechanism which prevents the simultaneous actuation of a register and said independent-ballet mechanism.

15. In a voting-machine, the combination of an independent-ballet mechanism with an actuator for said mechanism; an individual slide for said actuator; a register; a register-actuator; an individual slide for said register-actuator; a locking-slide moved by the operation of one of said actuators to prevent the subsequent operation of the other actuator; mechanism for preventing the simultaneous operation of said actuators; and mechanism for resetting.

16. In a voting-machine, the combination of an independent-ballet mechanism with an actuator for said mechanism; an individual slide for said actuator; a register; a register-actuator; an individual slide for said register-actuator; a locking-slide common to said actuator, said locking-slide and said individual slide limiting the movement of said actuators; mechanism for preventing the simultaneous operation of said actuators and mechanism for resetting.

17. In a question group, a pair of register-actuators; a pair of slides, one for each register-actuator, and notched to engage a locking-lever; and said locking-lever formed with ears and thereby adapted to engage one of said notched slides when actuated by the movement of the other of said notched slides.

18. In a question group, a pair of register-actuators; a pair of slides, one for each register-actuator, and notched to engage a locking-lever; said locking-lever formed with ears and thereby adapted to engage one of said notched slides when actuated by the movement of the other of said notched slides; and a resetting mechanism to disengage said locking-lever.

19. In a candidate group, the combination with a plurality of reg-

isters of register-actuators, one for each register; an individual slide for each register-actuator and reciprocated thereby; a plunger positively attached to each of said slides; mechanism for limiting the number of plungers which may be raised; and mechanism for resetting.

20. In a candidate group, the combination with a plurality of registers of register-actuators, one for each register; an individual slide for each register-actuator and reciprocated thereby; a plunger attached to each of said slides; abutments between which said plungers move; means for varying the free space between said abutments to limit the number of plungers which may be raised; and mechanism for resetting.

21. In an independent-ballet mechanism, a pair of cooperating rolls from one to the other of which the ballot-sheet passes; mechanism which positively engages with one of said rolls to turn said roll; and a lever under control of the voter for positively operating said mechanism in both directions.

22. In an independent-ballet mechanism, the combination of an actuating-slide under the control of the voter; means secured to said actuating-slide for exposing the ballot-sheet; a pair of cooperating rolls from one to the other of which the ballot-sheet passes; and means controlled by said actuating-slide for throwing said rolls into and out of operation.

23. In a voting-machine, the combination with a candidate group and means for operating the same of mechanism for feeding an independent-ballet sheet; an actuator for throwing said feeding mechanism into positive locking engagement with the resetting mechanism; means operated by said actuator for locking said candidate group; means operated by said actuator for exposing said ballot-sheet; and said resetting mechanism.

24. In an independent-ballet mechanism, the combination with an actuating-slide if a shutter secured to said actuating mechanism, and mechanism for resetting.

25. In an independent-ballet mechanism, the combination of a key-piece under control of the voter; a slide notched to engage said key-piece; a shutter secured to said slide; a pair of cooperating rolls from one to the other of which the ballot-sheet passes; mechanism controlled by said slide to throw said rolls into and out of operation; and resetting mechanism.

26. In an independent-ballet mechanism, the combination of an actuator under control of the voter; a pair of cooperating rolls for feeding the independent-ballet sheet; a pawl-and-ratchet mechanism for actuating said feed-roll; mechanism connecting said actuator with said pawl-and-ratchet mechanism to throw said pawl-and-ratchet mechanism into and out of operative connection with said feed-roll; mechanism operated by the voter on his exit to actuate said pawl-and-ratchet mechanism; and mechanism for resetting.

27. In a voting-machine, the combination with a group of registers and means for operating the same of a key-piece; an individual slide actuated by the rotation of said key-piece; a plate raised by said slide; locking means raised by said plate; and means for resetting said plate and said locking means.

28. In a voting-machine, the combination of a key-piece; a slide actuated by said key-piece; a plate; detachable means connecting said plate and slide; and means for connecting and disconnecting said slide to the independent-ballet mechanism.

29. In a voting-machine, the combination of a slide formed with a rack; catches detachably secured to said slide; a piston working with said rack; means for rotating said piston to throw said catches into engagement with locking means for a vote-registering mechanism; said locking means; and said vote-registering mechanism.

30. In a voting-machine, the combination with an independent-ballet mechanism of means for throwing said mechanism into and out of connection with a resetting mechanism; a yielding tripper connected to said resetting mechanism and operated thereby; and said resetting mechanism.

31. In a voting-machine, the combination of a standard formed with a bolt-hole; a bar pivoted in said standard and formed with a socket; a spring; a bolt; and a detent engaging said bolt.

32. In a voting-machine, the combination of a plurality of brackets; wires supported by said brackets; spacers threaded on said wires; and means for locking said spacers to said brackets.

33. In a voting-machine, the combination of a bracket; a separator; and a modified cylinder-latch mounted in said separator and adapted to engage said bracket.

34. In a voting-machine, the combination of a standard; a bar blinged in said standard; mechanism located within said bar for automatically locking said bar and said standard; means connected to a resetting mechanism for releasing said locking device when said resetting mechanism is operated; and said resetting mechanism.

35. In a voting-machine, the combination with a plurality of voting mechanisms of an exit-bar; a resetting mechanism operatively connected with said exit-bar to reset and lock said voting mechanisms; and an entrance-bar operatively connected with said resetting mechanism to unlock

said voting mechanisms, said resetting mechanism serving also to operatively connect said bars.

36. In an independent-ballet mechanism, a pair of cooperating rolls from one to the other of which the ballot-sheet passes, a lever operated by the voter for turning one of said rolls to feed the ballot-sheet; mechanism which connects said lever with said roll; and means under control of the voter to positively throw said connecting mechanism into and out of engagement with said roll.

686,926. ROTARY ENGINE. FRANK E. BATES, Philadelphia, Pa. Filed May 15, 1901. Serial No. 66,273. (No model.)

Claim.—1. The combination of a rotary engine comprising a cylinder with eccentric piston, sliding abutment and inlet and exhaust passages located one on one side and the other on the opposite side of said abutment, with a reversing-valve whereby the motive fluid may be directed to either of said passages, and valves whereby the escape from either passage may be regulated or cut off, the passages of the valves being so disposed that when the reversing-valve is directing steam to either side of the piston, the exhaust-valve on that side will be closed and the exhaust-valve on the other side will be open, and when the reversing-valve is adjusted to cut off the flow of steam, both exhaust-valves will likewise be closed, substantially as specified.

2. The combination of a rotary engine comprising a cylinder with eccentric piston, sliding abutment and inlet and exhaust passages located one on one side and the other on the opposite side of said abutment, with a reversing-valve whereby motive fluid may be directed to either of said passages, valves whereby the escape from either passage may be regulated or cut off, and connections between said valves and the reversing-valve whereby conjoint operation of the three valves is effected, the passages of the valves being so disposed that when the reversing-valve is directing steam to either side of the piston, the exhaust-valve on that side will be closed and the exhaust-valve on the other side will be open, and when the reversing-valve is adjusted to cut off the flow of steam, both exhaust-valves will likewise be closed, substantially as specified.

3. The combination, in a compound rotary engine, of the high and low pressure cylinders each with eccentric piston, sliding abutment and inlet and exhaust passages one on one side and the other on the opposite side of said sliding abutment, a reversing-valve having two chambers, one for each of the cylinders of the engine, and ports whereby each chamber may be caused to communicate with either of the passages of its corresponding cylinder, a receiving-chamber in communication with the low-pressure chamber of said reversing-valve, two exhaust-passages, a pair of duplex valves, one controlling the communication between the forward passage of the high-pressure cylinder and the receiving-chamber and between the forward passage of the low-pressure cylinder and an exhaust-passages, and the other controlling communication between the rear passage of the high-pressure cylinder and the receiving-chamber and between the rear passage of the low-pressure cylinder and an exhaust-passages, and connections between the reversing-valve and said controlling-valves whereby conjoint operation of the three valves is effected, substantially as specified.

4. The combination, in a compound rotary engine, of the high and low pressure cylinders each with eccentric piston, sliding abutment and inlet and exhaust passages one on one side and the other on the opposite side of said sliding abutment, a reversing-valve having two chambers, one for each of the cylinders of the engine, and ports whereby each chamber may be caused to communicate with either of the passages of its corresponding cylinder, a receiving-chamber in communication with the low-pressure chamber of said reversing-valve, two exhaust-passages, and a pair of duplex valves, one controlling the communication between the forward passage of the high-pressure cylinder and the receiving-chamber and between the forward passage of the low-pressure cylinder and an exhaust-passages, and the other controlling communication between the rear passage of the high-pressure cylinder and the receiving-chamber and between the rear passage of the low-pressure cylinder and an exhaust-passages, and connections between the reversing-valve and said controlling-valves whereby conjoint operation of the three valves is effected, substantially as specified.

5. The combination in a compound rotary engine, of the high and low pressure cylinders each with eccentric piston, sliding abutment and inlet and exhaust passages, one on one side and the other on the opposite side of said sliding abutment, a reversing-valve having two chambers, one for each of the cylinders of the engine, and ports whereby each chamber may be caused to communicate with either of the passages of its corresponding cylinder, a receiving-chamber, two exhaust-passages, a pair of duplex valves, one controlling the communication between the forward passage of the high-pressure cylinder and the receiving-chamber and between the forward passage of the low-pressure cylinder and an exhaust-chamber, and the other controlling communication between the rear passage of the high-pressure cylinder and the receiving-chamber and between the rear passage of the low-pressure cylinder and an exhaust-passages, and out-off valves, one controlling the flow of motive fluid to the high-pressure chamber of the reversing-valve, and the other controlling the flow of motive fluid from the receiver to the low-pressure chamber of said valve, substantially as specified.

6. The combination in a rotary engine, of a cylinder having therein an eccentric piston with peripheral ring mounted so as to be free to turn thereon, a sliding abutment with segmental head at its inner end mounted in a conical socket of said ring, and a cap-plate let into a recess in the ring and overlapping the segmental head of said sliding abutment so as to confine the same to the ring, substantially as specified.

686,927. LOCKING DEVICE FOR SWINGING HANDLES. RICHARD BARRETT, Amberg, Germany. Filed Nov. 2, 1901. Serial No. 66,064. (No model.)

Claim.—1. A fastener for the handles of culinary and other vessels, comprising ears of which one is bent substantially at right angle to form a horizontal portion and a vertical portion, said portions having communicating slots or openings at the bend, and said vertical portion having a notch therein; and a pivoted ball having one of its ends working over the surface of the vertical portion of the ear and dipping into the notch on turning the ball uprightly, said cam-like head being engaged by the slots of said notch and preventing oscillation of the vessel when lifted or carried by the ball.

2. A fastener for the handles of culinary and other vessels, comprising ears of which one is bent substantially at right angle to form a horizontal portion and a vertical portion, said portions having communicating slots or openings at the bend, and said vertical portion having a notch therein; and a pivoted ball capable of limited horizontal movement between the ears, and having one end thereof working over the surface of said vertical portion of the ear and dipping into the notch on turning the ball uprightly, said cam-like head being engaged by the slots of said notch when the vessel is lifted or carried by the ball, and said horizontal portion of the ear constituting a rest for the ball when turned downwardly in one side.

3. In fastenings for the handles of culinary or similar vessels, a bail-car having a notch and a pivot-rod for the end of the bail, and formed with a transverse portion having a slot communicating with each end; and a bail bent near one end to form a pivot working in said pivot-rod, and having a spring-like portion engaged by the sides of the notch when the bail is turned uprightly.

696,998. FOLDING HAY-BOX. BLANK C. BROWNE, East Moravia, Ohio. Filed Aug. 28, 1901. Serial No. 73,854. (No model.)

Claim.—1. A folding box comprising the sides 1 and 2 hinged together at the corners of the box, the sides 2 being crossed between the sides 1 and arranged to fold outward away from each other, whereby they are adapted to distend and place under tension an elastic connection, substantially as and for the purpose described.

2. A folding box comprising the sides 1 and 2 hinged together at the corners of the box, the sides 2 being crossed between the sides 1 and arranged to fold outward from each other, whereby they are adapted to distend a flexible connection, a folding bottom, and the folding top flaps hinged to the upper edges of the sides 2 and arranged to swing downward over the box, said top flaps being crossed between their side edges, whereby they are adapted to fold with the sides 2, substantially as described.

3. A folding box comprising the sides 1 and 2 hinged together at the corners of the box, the sides 2 being crossed between the sides 1 and arranged to fold outward from each other, whereby they are adapted to distend an elastic connection, the folding top flaps hinged to the upper edges of the sides 2 and crossed between their side edges to enable them to fold outward with the said sides 2, the folding bottom flaps hinged to the sides 1, and the continuous tape laced through the sides 2, the top flaps and the bottom flaps being adapted to be tied, substantially as and for the purpose described.

4. A folding box composed of sides hinged together at their adjacent edges, two of the sides being arranged to project outwardly from each other in folding, a folding bottom, an elastic connection arranged to be distended and placed under tension by the outwardly-projecting sides when the box is folded, whereby the said box, when released, will be automatically unfolded, and means for holding the box folded, substantially as described.

5. The combination of a folding box having sides 1 and 2 hinged together and arranged to fold outward, an elastic connection extending across the box and attached to the same adjacent to the said corners, whereby it is distended and placed under tension when the box is folded, and is capable of automatically unfolding the box when the parts of the latter are free to move, and a locking device for holding the box folded, substantially as described.

6. A folding box provided with sides arranged to fold outwardly away from each other and having notches, and an elastic band held within the notches and connecting the sides and arranged to be distended and placed under tension when the box is folded, substantially as and for the purpose described.

7. A folding box comprising the sides 1, the sides 2 hinged to the sides 1 and provided at their lower edges with notches, the folding bottom hinged to the sides 1, the top flaps, an elastic band arranged in the said notches and connecting the sides 2, and means for holding the box in its closed position, substantially as described.

696,999. CALF-WRINGER. GRANT C. BROWNE, Milwaukee, Wis. Filed Nov. 9, 1901. Serial No. 61,368. (No model.)

Claim.—1. In a calf-wringer, the combination of a guard or shield having upwardly-extending projections with a space therebetween, non-

engaging fingers along the upper edges of the projections, and having their inner ends adapted to extend into the space between the projections, one of said fingers provided with a circumferential recess, a bearing at the upper edge of one of the projections into which bearing the recessed finger is adapted to fit, a spring-dog adapted to extend into the bearing for said finger to contact with the inner wall of the recess of the finger when said finger is in position within its bearing, and an opening into said bearing through which said spring-dog may be released to permit the removal of said finger from said bearing.

2. In a calf-wringer, the combination of a guard or shield having upwardly-extending projections with a space therebetween, non-engaging fingers along the upper edges of the projections having their inner ends adapted to extend within the space between the projections, one of said fingers provided with a circumferential recess, a bearing at the upper edge of one of the projections, in which the recessed finger is adapted to fit, a spring-dog extending into the bearing for said finger and adapted to engage a wall of the recess of the finger when the finger is in its inward position and an opening into said bearing through which a suitable implement may be inserted to move said dog from engagement with said wall to permit the removal of said finger from its bearing.

3. In a calf-wringer, the combination of a guard or shield having upwardly-extending projections with a space therebetween, of non-engaging fingers arranged along the upper edges of said projections so as to extend into the space between said projections, a bearing member secured to one of said projections for loosely encircling one of said fingers, a circumferential recess in said encircled finger and a stop member adapted when said finger is in operative position to fit in said recess to prevent outward movement of said finger without preventing the same from rotating within its bearing.

4. In a calf-wringer, the combination of a guard or shield having upwardly-extending projections with a space therebetween, bearing members secured to the upper edges of the projections, non-engaging fingers loosely mounted in the bearing members, a slot in each bearing member extending a distance around the same and removable means secured to each finger and adapted to extend through said slot to prevent longitudinal movement of said finger without preventing the same from rotating in its bearing.

5. In a calf-wringer, the combination of a guard or shield having upwardly-extending projections with a space therebetween, bearing members secured to the upper edges of the projections, a non-engaging finger provided with a circumferentially-extending recess loosely mounted in each bearing and means extending into said recess for preventing longitudinal movement of said finger, without preventing the same from rotating in its bearing.

696,980. COMBINED SHADE-ROLLER AND CURTAIN-POLE BRACKET. LOUIS RABIN, Buffalo, N. Y., assignor of one-half to Frank Kiek, Buffalo, N. Y. Filed June 20, 1901. Serial No. 61,606. (No model.)

Claim.—1. A combined shade roller and curtain-pole bracket comprising longitudinally-slotted overlapping and relatively adjustable sections, means for clamping the overlapped portions of said sections together, shade-roller-supporting brackets provided with runners adjustable lengthwise of said sections, and longitudinally-extensible curtain-pole arms also provided with runners adjustable lengthwise of said sections.

2. A combined shade-roller and curtain-pole bracket comprising a bar consisting of longitudinally-slotted and relatively adjustable overlapping sections, a clamp for fastening the overlapping portions of said sections together, shade-roller brackets provided with runners adjustable

lengthwise of the bar-sections, and longitudinally-extensible curtain-pole arms having runners adjustable lengthwise on the bar-sections, each of said curtain-pole arms comprising an inner member having a bent and perforated outer end, and a sliding member in the form of a rod having a hook for the curtain-pole and having its shank slidably mounted in the perforated end of the inner member and provided at its inner end with a transverse slidable lengthwise of the inner member of the curtain-pole arm.

3. A combined shade-roller and curtain-pole bracket comprising a longitudinally-slotted bar consisting of overlapping and relatively adjustable sections, a flanged plate provided with a curved eye for clamping the overlapping ends of said sections together, shade-roller brackets adjustable lengthwise of the slotted bar, curtain-pole arms also adjustable lengthwise upon said bar, and means for connecting said bar to a window-frame and at the same time admitting of the relative adjustment of the sections thereof, said means comprising flanged plates adapted to be attached to the window-frame, screws or bolts projecting outward therefrom and adapted to be received in the slotted bar, flanged bar-holding plates mounted on said screws or bolts, and one or more retaining-nuts, substantially as described.

696,981. FIRE-ESCAPE. HERMAN BENTON, New York, Tex., assignor of one-half to Fritz Pressa, Lagrange, Tex. Filed Aug. 14, 1901. Serial No. 73,035. (No model.)

Claim.—1. A fire-escape comprising an inner frame designed to be arranged within a room and being of a length to extend from a point adjacent to the floor to a point above the top of a window, said frame being composed of side bars and suitable connecting-bars, an outer frame composed of side bars and suitable connecting-bars and hinged at its lower end to the inner frame at the lower portion thereof and arranged to swing outward to an inclined position to extend through a window, and capable of folding against the inner frame, folding braces connecting the frames and adapted to support the outer frame when the latter is in an inclined position, the platform hinged between the sides of the inner frame and arranged to swing between the same and adapted to swing outward and downward to a horizontal position and supported in such position by one of the connecting-bars of the outer frame, and means mounted on the outer frame for lowering persons or goods to the ground, substantially as described.

2. A fire-escape comprising inner and outer frames hinged together at the bottom and adapted to fold, the inner frame fitting against the inner face of a wall and provided with upright side bars and the outer frame being of a size to extend through a window, means mounted on the outer frame for lowering persons or goods to the ground, and a vertically-adjustable clamp composed of an inner jaw having a recess to receive the adjacent side of the inner frame and provided with a threaded opening, an outer jaw for engaging the exterior of the wall, and a screw passing through the threaded opening of the inner frame and connected with the outer jaw, substantially as described.

3. In a fire-escape, the combination of a frame, a shaft mounted thereon, grooved disks fixed to the shaft, ropes or cables reversely arranged on the grooved disks and coiled in the said grooves, the latter be-

ing of substantially the same width as the ropes or cables, whereby the shaft will be arranged in the same vertical plane, the reversely-arranged resilient guards covering a portion of the periphery of each disk and retaining the ropes or cables in the grooves, and a brake, substantially as described.

696,982. VOTING-MACHINE. ARTHUR J. DALY, San Francisco, Cal. Filed Mar. 20, 1901. Serial No. 625,923. (No model.)

Claim.—1. In a vote-recording machine, means for receiving the mechanism, said means comprising a grooved rod, said rod adapted to rotate or revolve the operated parts; a latch-bar connected with said rod to impart movement thereto, said latch-bar adapted to be tripped after being moved a predetermined distance, substantially as described.

2. In a voting apparatus, sections or units placed in series, one section having a series of straight-tick keys, other sections having a series of candidate-keys and counters; slotted confining rods traversing said sections, said rods operated by the straight-tick keys and acting on said counters; means independent of said rods, controlled by the candidate-key and acting on said counters, whereby votes may be cast for individual candidates without affecting the straight-tick mechanism, substantially as specified.

3. In a voting apparatus, a series of sections; said sections provided with counters; respective individual-candidate keys for operating said counters; a straight-tick section; said section provided with keys for operating each of said counters as were not cut out by substitution by said individual-candidate keys.

4. In a voting apparatus, sections or units placed in series, each provided with depressible voting-keys and counters, one section comprising straight-tick keys, other sections comprising keys and counters for individual candidates or measures, slotted confining rods passing through all the sections, each rod operated upon by a straight-tick key, said rods operating the aforementioned counters, and independent means for operating said counters controlled by the individual-candidate keys; in combination therewith, a rod passing underneath the individual-candidate keys and the levers of the straight-tick section, so that when said levers are operated the individual-candidate keys will become locked against operation.

5. In a voting apparatus, a series of individual-candidate sections, each provided with keys, levers and counters, a straight-tick section provided with keys and levers, confining rods traversing all said sections and operated by said straight-tick keys, one of said rods locking the individual-candidate keys and the remainder of said rods operating counters, means independent of said confining rods operated by the individual-candidate keys and operating the said counters, and a series of pendulous disks or wheels abutting against each other and movable laterally, in combination with the keys and levers of the several sections, whereby when one lever is depressed all the others in the series are obstructed against depression.

6. In a voting apparatus, a series of individual-candidate sections, each provided with keys, levers and counters, a straight-tick section provided with keys and levers, slotted confining rods traversing all sections and operated by the straight-tick keys, said rods operating the aforementioned counters, means independent of said confining rods operated by the individual-candidate keys and operating the said counters, and a series of pendulous pivoted disks abutting against each other and movable laterally, and a pawl and ratchet-wheel actuated by the last disk of the series and a pin-stop for limiting the number of movements made by the pendulous wheels and consequently the number of movements of the voting-keys.

7. In a voting apparatus, a series of sections; said sections provided with counters; respective individual-candidate keys for operating said counters; a straight-tick section, said section provided with keys for operating each of said counters as were not previously cut out by substitution by said individual-candidate keys; and a rod to release all levers operated.

8. In a voting apparatus, units or sections; said sections provided

bars and means of candidates with voting-mechanism adjacent; traversing said sections a series of rods for operating said counters independently of said individual-candidate keys; a rod for locking said keys against operation whether prior or subsequent to the operation of one or more of said keys; means to limit or predetermine the number of candidates that may be voted for in an office; means for maintaining said sections in their proper position.

59. In a voting apparatus, a series of interchangeable sections, one for each office, each section containing individual-candidate keys, counters and means of candidates with voting-mechanism adjacent; traversing said sections a series of rods for operating said counters independently of said individual-candidate keys; a rod for locking said keys against operation whether prior or subsequent to the operation of one or more of said keys; means to prevent voting for more than one candidate in an office; means to prevent voting for a candidate more than once; means for maintaining said sections in their proper position.

60. In a voting apparatus, a ball-crank for operating an individual-candidate counter, said ball-crank operable by an individual-candidate key, or by a straight-ticket key, each independently of the other.

61. A series of ball-cranks for operating corresponding counters, said ball-cranks operable by respective individual-candidate keys and by respective straight-ticket keys, each independently of the other.

62. A series of ball-cranks for operating corresponding counters, said ball-cranks operable by respective individual-candidate keys or by either of two or more straight-ticket keys, in combination therewith means to prevent the operation of any of said ball-cranks more than once or of more than one thereof.

63. A series of interchangeable sections, each section containing a series of individual-candidate keys, a straight-ticket section containing a series of keys and means for retaining said interchangeable sections in their proper position; traversing all sections a rod for locking said individual-candidate keys simultaneously with the operation of any of said straight-ticket keys.

64. In a voting-machine, a series of individual-candidate keys, a series of straight-ticket keys, means to prevent the operation of a straight-ticket key and an individual-candidate key at the same time, said means comprising a rocking rod and a straight-ticket key-lever with a projection thereon adapted to impart movement to said rod.

65. A series of counters individual-candidate keys for operating said counters, a series of straight-ticket keys and levers for operating said counters, a rod passing beneath all the individual-candidate keys and straight-ticket levers, the latter having a projection thereon to impart movement to said rod, thereby locking all individual-candidate keys.

66. A series of levers, means coacting to detain said levers when depressed, a series of pendulum disks chattering one against the other except the two that are operated by the depression of a lever, so as to lock the unoperated levers against depression; ball-cranks actuated by individual-candidate keys and connecting mechanism or straight-ticket keys and connecting mechanism, a stop-bar actuated by the individual-candidate key-levers to maintain the straight-ticket mechanism in a disengaged position.

67. In a voting apparatus, a series of sections, each containing individual-candidate keys, counters and means of candidates with voting-mechanism adjacent; corresponding with said keys a series of ball-cranks adapted to operate said counters by the operation of said keys; through these sections rods for operating said ball-cranks, and consequently said counters, independently of said individual-candidate keys.

68. A series of ball-cranks; individual-candidate keys for operating said ball-cranks; straight-ticket keys for operating said ball-cranks; means to prevent the operation of more than one of the ball-cranks of the series by any of said keys, said means comprising a series of disks or wards to prevent the operation of more than one straight-ticket key and a rod or bar adapted to lock all the individual-candidate keys of the series, accordingly as the individual-candidate key or the straight-ticket key is first operated.

69. A series of ball-cranks operable either by individual-candidate key-levers or by straight-ticket key-levers; a bar as described to prevent the operation of any ball-crank of the series by said straight-ticket key-levers subsequent to the operation of any one thereof by said individual-candidate key-levers.

70. In a voting apparatus, an individual counter means to operate said individual-candidate counter; additional means whereby said counter may be operated by either of two or more straight-ticket keys.

71. In a voting-machine, individual-candidate counters; respective keys for operating said counters; straight-ticket keys for operating said counters; means to prevent the operation of any of said counters more than once by said keys.

72. In a voting-machine, a series in series and protect the mechanism;

candidate-counters; respective individual-candidate keys for operating said counters; voting-mechanism to identify said keys with said counters; straight-ticket keys to operate said counters independently of said individual-candidate keys.

73. In a voting-machine; candidate-counters; respective individual-candidate keys for operating said counters; voting-mechanism to identify said keys and counters; straight-ticket keys for operating said counters independently of said individual-candidate keys.

74. In a vote-recording machine, means for receiving the mechanism, comprising a rod adapted to release or reset the operated parts; connected with said rod a deflected latch-bar; a guide for said latch-bar so as to trip said latch-bar when moved a predetermined distance; means to impart movement to said latch-bar, substantially as described.

75. In a voting-machine, a series of counters; individual-candidate keys to operate said counters; straight-ticket keys to operate said counters; a bar operated by said individual-candidate keys to prevent the operation of said counters by any of said straight-ticket keys when operated.

76. In a voting-machine, a series of counters; individual-candidate keys to operate said counters; straight-ticket keys to operate said counters independently of said individual-candidate keys; a bar operated by said individual-candidate keys to prevent the operation of said counters by any of said straight-ticket keys when operated.

77. In a voting-machine, a series of counters; individual-candidate keys to operate said counters; straight-ticket keys to operate said counters; a bar operated by said individual-candidate keys to prevent the operation of said counters by any of said straight-ticket keys when operated; a rod coacting with said straight-ticket keys to lock said individual-candidate keys.

78. In a voting-machine, a series of counters; individual-candidate keys to operate said counters; voting-mechanism to identify said keys and counters; straight-ticket keys to operate said counters; a bar, operated by said individual-candidate keys, to prevent the operation of said counters by any of said straight-ticket keys when operated.

79. In a voting-machine, a series of counters; individual-candidate keys to operate said counters; voting-mechanism to identify said keys with said counters; straight-ticket keys to operate said counters independently of said individual-candidate keys; a bar operated by said individual-candidate keys to prevent the operation of said counters by any of said straight-ticket keys when operated.

80. In a voting-machine, keys for voting for individual candidates irrespective of party; means, independent of said keys, for voting the remainder of any party-ticket.

81. In a voting-machine, keys for voting for individual candidates irrespective of party; means independent of said keys, for voting the remainder of any party-ticket at a single operation.

82. In a voting-machine, a series of rods; transversely therewith a series of sliding bars; said bars provided with lugs, said lugs staggered on said bars to engage with said rods as the slugs may require; flexible pawls on said bars; a bar to depress said pawls.

83. In a voting-machine, segregable sections; said sections containing keys for voting for individual candidates irrespective of party; means, independent of said keys, for voting the remainder of any party-ticket.

84. In a voting-machine, a series of individual-candidate sections, comprising keys and levers for operating respective counters; a straight-ticket section provided with keys and levers for operating said counters; traversing said sections an oscillating rod adapted to release all levers operated; in combination therewith a bar to prevent the operation of the counters, in an individual-candidate section wherein one of the counters has been operated by an individual-candidate key, by said straight-ticket key-levers.

85. In a voting-machine, means to operate an individual-candidate counter by either of two or more straight-ticket keys.

86. In a voting-machine, a series of counters; individual-candidate keys to operate said counters; means whereby any of said counters may be operated by either of two or more straight-ticket keys.

87. In a voting-machine, a series of individual-candidate keys; a rod for locking said keys against operation; a series of straight-ticket levers with projections thereon to impart movement to said rod; a series of wards to prevent the operation of more than one of said levers at a time, substantially as described.

88. In a voting apparatus, a series of sections; said sections provided with counters; respective individual-candidate keys for operating said counters; a straight-ticket section; said section provided with keys for operating each of said counters as may comprise a straight ticket, or the unvoted portion thereof, independently of said individual-candidate keys.

89. In a voting apparatus, a series of individual-candidate counters; respective individual-candidate keys to operate said counters; straight-ticket keys to operate said counters; means whereby said counters may

be operated by either of two or more of said straight-ticket keys; in combination with means to prevent the operation of any of said counters more than once, or of more than one of the series, by any of said keys, substantially as described.

90. In a voting-machine, the means for voting a split ticket, comprising individual-candidate keys; ticket-keys; means coacting with the inwardly portion of said keys whereby a portion of said split ticket may be voted by said candidate-keys and a portion of said split ticket may be voted by said ticket-keys.

91. In a voting-machine, a casing to contain the mechanism; individual-candidate counters; candidate-keys to operate said counters; ticket-keys to operate said counters, said keys operating partially within and partially without said casing and so projecting therefrom that said keys may be operated; mechanism coacting with the inwardly portion of said keys whereby the whole or a portion of each of said counters as comprise a party-ticket may be operated by the operation of one of said ticket-keys.

92. In a voting-machine, a casing to contain the mechanism; individual-candidate counters; candidate-keys to operate said counters; ticket-keys to operate said counters, said keys operating partially within and partially without said casing and so projecting therefrom that said keys may be operated; mechanism coacting with the inwardly portion of said keys whereby the whole or a portion of each of said counters as comprise a party-ticket may be operated by the operation of one of said ticket-keys; mechanism to prevent voting for a candidate more than once.

93. In a voting-machine, a casing to contain the mechanism; individual-candidate counters; candidate-keys to operate said counters, said keys operating partially within and partially without said casing and so projecting therefrom that said keys may be operated; party-keys; mechanism coacting with the inwardly portion of said keys whereby the whole or a portion of each of said counters as comprise a party-ticket may be operated by the operation of one of said ticket-keys; means to prevent voting for more than one candidate in an office.

94. In a voting-machine, a casing to contain the mechanism; individual-candidate counters; candidate-keys to operate said counters; ticket-keys to operate said counters, said keys operating partially within and partially without said casing and so projecting therefrom that said keys may be operated; mechanism coacting with the inwardly portion of said keys whereby the whole or a portion of each of said counters as comprise a party-ticket may be operated by the operation of one of said ticket-keys; mechanism to limit or predetermine the number of candidates that may be voted for in an office.

95. In a voting-machine, the means for voting a split ticket, comprising a casing, candidate-keys, ticket-keys, said keys partially projecting and partially within said casing, means coacting with the inwardly portion of said keys whereby a portion of said split ticket may be voted by said candidate-keys and a portion thereof by said ticket-keys.

96. In a voting-machine, means for voting for individual candidates irrespective of party; ticket-keys; mechanism for voting the portion of any party-ticket, not otherwise voted, by the operation of one of said keys; said mechanism so disposed as to be operable only through the medium of said ticket-keys.

97. In a voting-machine, means for voting for individual candidates irrespective of party; ticket-keys; mechanism for voting the portion of any party-ticket, not otherwise voted, by the operation of one of said keys; said mechanism so disposed as to be operable only through the medium of said ticket-keys; means to prevent voting for a candidate more than once; means to limit or predetermine the number of candidates in an office; means to limit or predetermine the number of candidates that may be voted for in an office; means to reset the operated parts, substantially as described.

98. In a voting-machine, a casing; ticket-keys; said keys operating partially within and partially without said casing and so projecting therefrom that said keys may be operated; means coacting with the inwardly portion of said keys whereby the whole or a portion of a party-ticket may be voted by the operation of a ticket-key.

99. In a voting-machine, ticket-keys; mechanism coacting therewith whereby the whole or a portion of a party-ticket may be voted by one of said keys; means whereby a candidate may be voted for by either of two or more of said keys.

100. In a voting-machine, candidate-keys; ticket-keys; and mechanism so disposed as to prevent removal of the parts thereof coacting with said keys whereby a portion of a split ticket may be voted by said candidate-keys and a portion thereof by said ticket-keys.

101. In a voting-machine, the means for voting a split ticket, comprising counters for individual candidates; corresponding keys for operating said counters; ticket-keys for operating said counters; mechanism coacting with said keys whereby a portion of said split ticket may be ascertained on said counters by said individual-candidate keys, and a portion thereof by said ticket-keys, said mechanism so disposed as to prevent the operation of said coacting mechanism, or any of the parts thereof, except by said keys.

102. In a voting-machine, the means for voting a split ticket, comprising a casing, candidate-keys, ticket-keys, said keys partially projecting and partially within said casing, means coacting with the inwardly portion of said keys whereby a straight ticket may be voted by said ticket-keys, or whereby a portion of said split ticket may be voted by said candidate-keys and a portion thereof by said ticket-keys.

696,988. DRIVING MECHANISM FOR SEWING-MACHINES. BROWN, BENJAMIN, PROVIDENCE, R. I., and ORIN A. BROWN, BRIDGEPORT, CONN., assignors to WILCOX & GIBBS SEWING MACHINE COMPANY, NEW YORK, N. Y., a Corporation of New York. Filed Jan. 26, 1891. Serial No. 41,882. (20 claims.)

Claim.—1. The combination with the driving-shaft and back-shaft, the pulleys having peripheral pins, and the perforated belt, of a belt-guard adjacent to the driven pulley for preventing the belt slipping off the pin.
2. The combination with the back-shaft and pin-pulley thereon, and with the perforated driving-belt, of a belt-guard having a surface adjacent to said pulley, but normally out of contact with said belt, said surface having a groove or recess for entrance of the pin.
3. The combination with the back-shaft, driven pulley thereon having peripheral pins, and driving-belt having perforations engaging said pins, of a belt-guard comprising a grooved metal tongue adjacent to said pulley.
4. The combination with the back-shaft, driven pulley thereon having peripheral pins, and driving-belt having perforations engaging said pins, of a belt-guard, comprising a curved metal plate having a stationary guard-surface extending partly around said pulley, and having a groove or recess for entrance of the pin.
5. The combination with the driving-pulley on the main shaft and the driven pulley on the back-shaft, said pulleys having peripheral pins, and with the connecting-belt having perforations to engage said pins, of the grooved belt-guard adjacent to said driving-pulley.

696,984. SUGAR-SHIFT FULLER AND TUPPER. CHARLES W. HANLEY, LYONS, N. Y. Filed June 26, 1891. Serial No. 66,896. (No model.)

Claim.—1. In a beet-harvester, the combination with a pair of spaced plows, a pair of spaced fingers between the plows and whose front ends spread outward, and a carrier comprising a pair of endless chains whose inner active sides stand above the fingers and at an angle to each other and have open projecting toward each other; of connections between the main axle and chains for imparting movement to the latter, and means for raising and lowering the plows and the fingers, all substantially as described.

2. In a beet-harvester, the combination with a pair of spaced plows and a pair of spaced fingers all mounted on the framework of the machine, two pairs of axle chains to each other, means for adjusting one of each pair, and endless chains mounted on rollers on said axle with their active sides spread and leading from over the fingers upward to the rear of the machine; of a spur-wheel located within each chain about

midway between its rollers, and connections between the shaft of this wheel and the main axle, all substantially as described.

3. In a best-harvester, the combination with the main framework, and the digging mechanism at the forward end thereof; of a carrier comprising two endless chains whose active sides are spaced and stand oblique to each other, rollers in the heads of these chains, and for each chain a spur-wheel between its sides about midway of its length, a bearing supporting the shaft of this wheel and standing against the edge of the chain, a counter-shaft in a bearing, intermeshing gears connecting the two shafts, and gearing also between the counter-shaft and the main axle of the machine, all as and for the purpose set forth.

4. In a best-harvester, the combination with the digging mechanism, and a carrier for conveying the beets therefrom; of a topping-knife located above the carrier and supported by a movable frame, and a roller in said frame resting on the beets, as and for the purpose set forth.

5. In a best-harvester, the combination with the digging mechanism, and a carrier for conveying the beets therefrom; of a topping-knife located above the carrier, a frame for the knife pivoted to standards on the main framework and having slotted bearings, and a roller extending across the carrier and whose shaft is adjustably mounted in said bearings, as and for the purpose set forth.

6. In a best-harvester, the combination with the digging mechanism, and a carrier for conveying the beets therefrom; of a frame pivoted to standards rising from the main framework, a topping-knife and a roller carried by said frame, a header whose shaft is journaled in the frame and whose arms operate between the roller and knife, and connections between said header-shaft and the main axle of the machine, substantially as described.

7. In a best-harvester, the combination with the digging mechanism, and a carrier for conveying the beets therefrom; of a frame pivoted to standards rising from the main framework, a topping-knife and a roller carried by said frame, a header whose shaft is journaled in the frame and whose arms operate between the roller and knife, a pulley and sprocket journaled on the pivot between one side bar of the frame and its standard, a belt connecting this pulley with a pulley on the header-shaft, and a chain belt connecting this sprocket with a sprocket on the main axle, as and for the purpose set forth.

8. In a best-harvester, the combination with the digging mechanism, and a carrier for conveying the beets therefrom; of a frame pivoted to standards rising from the main framework, a roller standing across the carrier and whose shaft is vertically adjustable in bearings in said frame, a knife extending obliquely across above the carrier and whose extremities are adjustably tilted in slots in said frame, a header whose shaft is

journaled in the frame and whose arms operate between the roller and knife, and connections between said header-shaft and the main axle of the machine, all substantially as and for the purpose set forth.

696,985. PICTURE-FRAME. FRANK A. BUSHNER, Rutland, Vt., assignor to the Bushner Manufacturing Company, Rutland, Vt. Filed May 22, 1901. Serial No. 61,533. (No model.)

Claim.—1. In a picture-frame, the combination of strips or sections of sheet metal A, with outwardly and rearwardly turned flanges A' on their inner edges suitably perforated at intervals, their ends being suitably mitered to form corners; corner-plates E of sheet metal; and a suitable solder between said sections and said corner-plates, as specified.

2. In a picture-frame, the combination of strips or sections of sheet metal A, with outwardly and rearwardly turned flanges A' on their inner edges, their ends being suitably mitered to form corners; corner-plates E of sheet metal; and a suitable solder between said sections and said corner-plates, as specified.

3. In a picture-frame, the combination of strips or sections of sheet metal with outwardly and rearwardly turned flanges on their inner edges suitably perforated at intervals their ends being suitably mitered to form corners; corner-plates E of sheet metal; suitable solder between said sections and said corner-plates; and rolls of sheet metal D having corner-sections D' cleaved upon the same, slotted to embrace the outer edges of the sections A and secured thereon, as specified.

4. In a picture-frame, the combination of strips or sections of sheet metal with outwardly and rearwardly turned flanges on their inner edges, their ends being suitably mitered to form corners; corner-plates E of sheet metal; suitable solder between said sections and said corner-plates; and rolls of sheet metal D having corner-sections D' cleaved upon the same, slotted to embrace the outer edges of the sections A and secured thereon, as specified.

5. In a picture-frame, the combination of strips or sections of sheet metal with outwardly and rearwardly turned flanges on their inner edges suitably perforated at intervals, their ends being suitably mitered to form corners; corner-plates E of sheet metal; suitable solder between said sections and said corner-plates; rolls of sheet metal D having corner-sections D' cleaved upon the same, slotted to embrace the outer edges of the sections A and secured thereon; and strips of metal C soldered in position against the outwardly-turned portion of the said flanges of said sections, for the purpose specified.

6. In a picture-frame, the combination of strips or sections of sheet metal with outwardly and rearwardly turned flanges on their inner edges, their ends being suitably mitered to form corners; corner-plates E of sheet metal; suitable solder between said sections and said corner-plates; rolls of sheet metal D having corner-sections D' cleaved upon the same, slotted to embrace the outer edges of the sections A and secured thereon, and strips of metal C soldered in position against the outwardly-turned portion of the said flanges of said sections, for the purpose specified.

7. In a picture-frame, the combination of two or more rectangular frames of sheet metal with outwardly and rearwardly turned flanges on their inner edges, the said frames being graded in size so that the outer edge of the one will fit within the said flanges on the inner edge of the other; and means of securing the said frames in such position, for the purpose specified.

8. In a picture-frame, the combination of two or more rectangular frames of sheet metal with outwardly and rearwardly turned flanges on their inner edges, the said frames being graded in size so that the outer edge of the one will fit within the said flanges on the inner edge of the other; means of securing the said frames in such position; perforations in the flanges of the inner frame; and strips of sheet metal C secured in position against the outwardly-turned portion of said flanges, for the purpose specified.

9. In a picture-frame, the combination of two or more rectangular frames of sheet metal with outwardly and rearwardly turned flanges on

their inner edges, the said frames being graded in size so that the outer edge of the one will fit within the said flanges on the inner edge of the other; means of securing the said frames in such position; perforations in the flanges of the inner frame; for the purpose specified.

10. In a picture-frame, the combination of two or more rectangular frames of sheet metal with outwardly and rearwardly turned flanges on their inner edges, the said frames being graded in size so that the outer edge of one will fit within the said flanges on the inner edge of another; means of securing the said frames in such position; perforations in the said flanges of the inner frame; and a roll of sheet metal slotted to embrace the outer edge of the outer frame and secured thereon for the purpose specified.

11. A picture-frame made up of strips of sheet metal suitably joined together, the inner edges of which are turned outwardly and rearwardly to form a flange to receive the back of the picture-frame or picture-back, as specified.

696,986. BOX. LEO J. BUSHNER, Sturgis, Mich. Filed Jan. 3, 1901. Serial No. 41,987. (No model.)

Claim.—1. In a box, the combination of the bottom A; sides A', mid bottom and sides being formed of a single piece suitably scored, and having flaps c on each end adapted to fold, said flaps being suitably notched at c'; and piece B, secured on the inner face of said flaps; and said piece B' fitted and secured between the edges of said flaps, for the purpose specified.

2. In a box, the combination of the bottom and side pieces with flaps on each end thereof; an end piece of a size and shape to fit inside of said box secured on the inner face of said flaps; and an exterior end piece of a size and shape to fit between the edges of the said flaps secured to the same, as specified.

696,987. GRATE-BAR FOR FORCED-BLAST FURNACES. FRANK BUSHNER and HENRY M. WILLIAMS, Port Wayne, Ind.; said Bushner assignor of one-half his right to said Williams. Filed May 26, 1900. Serial No. 17,731. (No model.)

Claim.—1. A grate consisting of separated grate-bars each provided with a vertical central channel for the passage therethrough of air, and air-conductors arranged beneath said bars in a position to direct a blast of air upward through said central channels, substantially as described.

2. A grate consisting of separated grate-bars each provided with a vertical central channel having a tortuous opening at the top for the passage therethrough of air, and air-conductors arranged beneath the bars in a position to direct a blast of air upward through said channels, substantially as described.

3. In a grate, the combination of a series of grate-bars each composed of two pieces connected together to form between them a vertical central channel for the passage of air, and an air-conductor below each bar arranged to direct currents of air upward through the bars, substantially as described.

4. The combination in a grate, of a series of separated channelled bars, a series of air-conductors below said bars, and an air pipe or chamber extending around the grate and communicating with the opposite ends of the air-conductors, substantially as set forth.

696,988. MULTICOLOUR-PRINTING PRESS. JOHN R. GARD, Kansas City, Mo. Filed Mar. 2, 1901. Serial No. 60,372. (No model.)

Claim.—1. The combination with a graduated press-cylinder, and a distributor-shaft having graduations corresponding to the graduations of the cylinder, of a distributing-cylinder comprising adjustable cylinder-sections mounted upon the shaft and adapted to be set by the graduations thereof, means for setting a type form or plate upon the press-cylinder by the graduations thereof, to secure the proper relation between the form and distributing-cylinder, a subdivided ink-fountain designed to contain ink of different colors, and means for transferring ink from the fountain to the distributing-cylinder and from said distributing-cylinder to the type-form.

2. In a printing-press, the combination with a graduated ink-fountain, a graduated distributor-shaft, and a graduated press-cylinder, the latter being designed for the reception of the type form or plate, and the graduations of the several graduated elements being correlative, of adjustable partitions for the fountain, adjustable disks constituting a distributor-cylinder for the distributor-shaft, adjustable means for securing the form or plate upon the cylinder, distributing-rolls intermediate of the fountain and distributor-cylinder, and form-rolls intermediate of the distributor-cylinder and form.

3. In a printing-press, the combination with an ink-fountain, a press-cylinder, distributing-rolls, and form-rolls, of a vibratory lateral distributor, a vibrating arm operatively related thereto, a vibrator, a regular-black adjustable thereon, a regulating-rod disposed to shift said black, and a link having pivotal connection at its opposite ends with the regulating-black and vibrating arm respectively.

4. In a printing-press, the combination with an ink-fountain, a press-cylinder, distributing-rolls, and form-rolls, of a vibratory lateral distributor, driving and driven arms, said driven arm having an operative connection with the distributor, a vibrator furnished intermediate of its ends, and links connected at their inner ends to the driving and driven arms, respectively, and at their outer ends to the vibrator at opposite sides of the axis thereof.

5. In a printing-press, the combination with an ink-fountain, a press-cylinder, distributing-rolls, and form-rolls, of a vibratory lateral distributor, oscillatory driving and driven arms, said driven arm having an operative connection with the distributor, a vibrator operatively connected with the driving-arm and designed to be driven thereby, and a shiftable connection between said vibrator and the driven arm.

6. In a printing-press, the combination with an ink-fountain, a press-cylinder, distributing-rolls, and form-rolls, of a vibratory lateral distributor, oscillatory driving and driven arms, said driven arm having an operative connection with the distributor, a vibrator operatively connected with the driving-arm and designed to be driven thereby, and a shiftable connection between said vibrator and the driven arm.

7. In a printing-press, the combination with an ink-fountain, a press-cylinder, distributing-rolls, and form-rolls, of a vibratory lateral distributor, driving and driven arms furnished at their contiguous ends, one of said arms having operative connection with the distributor, a vibrator, links having connection at their opposite ends with the arms and the vibrator respectively, and a link-shifter constituting a connection between one of the links and the vibrator.

8. In a printing-press, the combination with an ink-fountain, a press-cylinder, distributing-rolls, and form-rolls, of a vibratory lateral distributor, a driving-arm connected therewith, a vibrator furnished at a point intermediate its ends, and provided with an arcuate guideway intersecting the axis of movement of the vibrator, a regular-black movable in said guideway, a link connected at its opposite ends to said black and to the driven arm respectively, and driving mechanism connected to one end of the vibrator.

9. In a printing-press, the combination with an ink-fountain, a press-cylinder, distributing-rolls, and form-rolls, of a vibratory lateral distributor, driving and driven arms having a common fulcrum at their contiguous ends, the driven arm being connected to the vibratory distributor to ef-

test the vibration thereof without effecting its rotary movement, a vibrator submersed at a point intermediate of its ends and having an arcuate guideway intersecting the axis of the vibrator, a regulator-block movable in the guideway, links connected at their inner ends to the driving and driven arms, and at their outer ends to the vibrator and regulator-block respectively, a regulating-arc connected to the regulator-block to shift the same, and a swinging bearing for said arc.

10. A lateral distributor for multicolor-printing process, comprising a distributor-shaft provided with a keyway, a plurality of disks loosely mounted on said shaft, each of said disks being provided with a key-cocket having a reduced internally-threaded portion, and a key seated within the key-cocket and comprising a cylindrical body portion, a reduced threaded end engaging the threaded portion of the cocket and extending into the keyway, and a reduced squared end at the opposite extremity of the cylindrical body portion, and a removable key-section designed to be inserted into the key-cocket of the disk and to engage the reduced squared end of the key proper.

11. In a printing-press, the combination with a vibratory lateral distributor, driving mechanism, and an oscillatory vibrator, of connecting devices connecting the vibrator at opposite sides of its pivot with the distributor and driving mechanism respectively, one of said connecting devices having adjustable connection with the vibrator.

12. In a printing-press, the combination with a vibratory lateral distributor, and an oscillatory vibrator having connection at opposite sides of its pivot with the distributor and driving mechanism, respectively, of a regulating device adjustable upon the oscillatory vibrator, said regulating device being arranged to shift the connection between the distributor and vibrator.

13. In a printing-press, the combination with a vibratory lateral distributor, driving mechanism, and an oscillatory vibrator connected at opposite sides of its pivot to the distributor and driving mechanism, respectively, of a regulator-block adjustable upon the vibrator and constituting a part of one of the connections, and means for shifting said block.

14. In a printing-press, the combination with a vibratory lateral distributor, and driving mechanism, of an arm connected to the distributor, a separate independently-movable arm connected to the driving mechanism, and an oscillatory vibrator connected to said arms at opposite sides of its pivot, the connection with one of said arms being adjustable.

15. In a printing-press, the combination with a vibratory lateral distributor and driving mechanism, of independent oscillatory arms having a common pivot and connected to the regulator and driving mechanism respectively, and regulating mechanism disposed to transmit motion from one arm to the other, said mechanism being arranged to adjust the relative throw of the arms.

16. In a printing-press, the combination with a vibratory lateral distributor and driving mechanism, of independent oscillatory arms having a common pivot and connected respectively to the regulator and driving mechanism, an oscillatory vibrator having connection at opposite sides of its pivot with said arms, and means carried by the vibrator for shifting one of said connections to regulate the relative throw of the arms.

17. A lateral distributor for multicolor-printing process comprising a distributor-shaft provided with a keyway, a plurality of disks loosely mounted on said shaft, each of said disks being provided with a key-cocket, a key seated within the key-cocket and extended into the keyway, and a removable key-section designed to be inserted into the key-cocket of the disk to engage the key proper.

18. A lateral distributor for multicolor-printing process comprising a distributor-shaft provided with a keyway, a plurality of disks loosely mounted on said shaft, each of said disks being provided with a key-cocket having a reduced terminal threaded portion, and a key seated within the key-cocket and comprising a cylindrical body portion, a reduced threaded end engaging the threaded portion of the cocket and extended into the keyway, and a reduced squared end at its opposite extremity.

696,989. SCRAPPER FOR DOUGLASS CUTTING MACHINES. J. L. GARDNER, Kansas City, Mo. Filed Jan. 2, 1902. Serial No. 57,595. (No model.)

Claim.—1. The combination of a cutting-machine having a traveling belt on which the dough is carried, and a scraper, comprising a toothed wheel or disk engaging the dough, and rotating in substantially the same direction that the dough is moving.

2. The combination of a cutting-machine, having a traveling belt on which the dough is carried, and a scraper, comprising a toothed wheel or disk engaging and turned by the moving dough.

3. The combination of a cutting-machine, having a traveling belt on which the dough is carried, and a scraper comprising a shaft extending upwardly and inwardly over the dough, and a toothed wheel or disk journaled on said shaft and engaging the dough.

4. The combination of a cutting-machine, having a traveling belt on which the dough is carried, and a scraper, comprising a rotatably-adjustable shaft extending upwardly and inwardly over the dough, and a toothed wheel or disk journaled on said shaft and engaging the dough.

5. The combination of a cutting-machine, having a traveling belt on which the dough is carried, and a scraper, comprising a longitudinally-adjustable shaft extending transversely of and upwardly and inwardly over the dough, and a toothed wheel or disk journaled on said shaft and engaging the dough.

6. The combination of a cutting-machine, having a traveling belt on which the dough is carried, and a scraper, comprising a shaft extending transversely of the belt and upwardly and inwardly over the same, and adjustable both longitudinally and rotatably, and a toothed wheel or disk journaled on said shaft and engaging the dough.

7. The combination of a cutting-machine, having a traveling belt on which the dough is carried, and a scraper comprising a yoke-acting detachably clamped to the cutting-machine frame, a shaft rotatably and longitudinally adjustable in said yoke, and provided with an arm extending upwardly and inwardly over the dough, and a toothed wheel or disk journaled on said shaft and engaging the dough.

8. The combination of a cutting-machine, having a traveling belt on which the dough is carried, and a scraper comprising a shaft extending upwardly and inwardly over the dough, a toothed wheel or disk journaled on said shaft and engaging the dough, and a collar adjustable on the shaft and supporting the toothed wheel or disk at the desired elevation.

696,940. THROUNDER-HANGER. MARION H. CAMER, Chicago, Ill. Filed Jan. 2, 1902. Serial No. 58,220. (Model.)

Claim.—1. A thrasher-hanger comprising a pair of suspending spring-arms, clamping-jaws formed of a pair of elongated strips or arms pivoted to the spring-arms so as to be placed in a position at an angle thereto or approximately parallel therewith, whereby the device may be folded into compact form for shipment, and means for locking the jaws together.

2. In a thrasher-hanger, the combination of spring suspending-arms integrally formed at an angle to each other, arched spring leg-clamping jaws pivotally attached to arms so as to fold thereunder or to be placed at a normally operative angle thereto, means for adjustably locking said jaws and arms at said normally operative angle, means for locking the said jaws together, substantially as shown and described.

3. In a thrasher-hanger, the combination of spring suspending-arms integrally formed at an angle to each other, leg-clamping jaws pivotally attached to the extremities of said arms so as to be normally out of engagement with each other, the said jaws and arms being provided with an offset in the one and a depression in the other adapted for mutual engagement, spring means for keeping said offset and depression in engagement, and means for locking the said jaws together, substantially as shown and described.

4. In a thrasher-hanger, the combination of spring suspending-arms integrally formed at an angle to each other, arched spring leg-clamping jaws pivotally attached to the extremities of the said arms so as to be normally out of engagement with each other, the said jaws and arms being provided with an offset in the one and a depression in the other adapted for mutual engagement, spring means for keeping said offset and depression in engagement, and means for locking the said jaws together, substantially as shown and described.

die in engagement, and means for locking the said jaws together, substantially as shown and described.

5. A thrasher-hanger comprising two opposed elongated clamping-jaws formed of spring-metal strips, arched from end to end so as to engage the interposed fabric near their ends, said jaws being adapted to close together to stretch the fabric in the direction of the length of the jaws, a V-shaped suspending-spring, upon the ends of which said clamping-jaws are mounted, a hook at the apex of the suspending-spring, and a link or chain adapted to slide over the arms of the suspending-spring to maintain the same and hold the jaws closed upon the fabric.

6. In a thrasher-hanger a combination of spring suspending-arms integrally formed at an angle to each other, arched spring leg-clamping jaws pivotally attached to the extremities of said arms, the said jaws and arms being provided with an offset in the one and a depression in the other adapted for mutual engagement, a spring-weather under the head of the pivotally-attached rivet so as to permit the said depression and offset to be thrown out of engagement, and means for closing the said jaws together, substantially as shown and described.

696,941. MANUFACTURE OF ARMOR-PLATE. GEORGE CHART, Mulhouse, France, assignor to Co. des Forges de Châtillon, Commantry at Neuve-Maison, Paris, France. Filed Sept. 25, 1901. Serial No. 75,120. (No specimen.)

Claim.—1. As a new article of manufacture, an armor-plate of steel containing about five per cent. of nickel and from 0.1 to 0.15 per cent. of carbon, cemented on one face only, and hardened at a temperature of about 750° to 800° centigrade without subsequent annealing, whereby after hardening the cemented face has a porcelain-like texture and hardness, and the remainder of the mass has a non-facile texture.

2. As a new article of manufacture, an armor-plate of steel containing about five per cent. of nickel, from 0.1 to 0.15 per cent. of carbon, and about 0.5 per cent. of chromium, cemented on one face only, and hardened at a temperature of about 750° to 800° centigrade without subsequent annealing, whereby after hardening the cemented face has a porcelain-like texture and hardness, and the remainder of the mass has a non-facile texture.

3. The process of manufacturing armor-plates which consists in treating a plate of steel containing about five per cent. of nickel and from 0.1 to 0.15 per cent. of carbon, to cementation on one face only, and then hardening at a temperature of about 750° to 800° centigrade without subsequent annealing, whereby the cemented face is given a porcelain-like texture and hardness and the remainder of the mass has a non-facile texture.

696,942. GUN-SIGHT. ROBERT CHAMBER, Burning Springs, Ky. Filed Nov. 28, 1901. Serial No. 54,894. (No model.)

Claim.—1. In a gun-sight, a base-plate, and ears rising from the opposite sides thereof; combined with a standard carrying the sight proper, a head at the lower end of the standard fitting closely between said ears, means for holding the standard in an elevated or depressed position, and a pivot comprising a tapering conical body passing through one ear and through the head and a threaded tip engaging the other ear, so as to be for the purpose set forth.

2. A gun-sight comprising two main members longitudinally dotted in places at right angles to each other and the smaller member of a shape to telescope within the larger, and an adjusting-arc connecting the arms of the larger member and passing across the dot in the larger and immediately loosely through the dot of the smaller member; combined with a base on which one member is pivotally supported, and a sight proper carried by the other member.

3. A gun-sight comprising two main members longitudinally dotted in places at right angles to each other and the smaller member of a shape to telescope within the larger; combined with a support for the lower end of the larger member, a sight proper at the upper end of the smaller

member, a ferrule surrounding the upper end of the larger member, and a set-screw passing transversely through said ferrule and the arm of the larger member, across the dot in the latter, and through the dot in the smaller member.

4. A gun-sight comprising two main members longitudinally dotted in places at right angles to each other and the smaller member of a shape to telescope within the larger; combined with a support for the lower end of the larger member, a sight proper at the upper end of the smaller member, a ferrule surrounding the upper end of the larger member, and a set-screw passing transversely through said ferrule and the arm of the larger member, across the dot in the latter, and loosely through the dot in the smaller member, the tip of said screw engaging a threaded hole in the ferrule, so as to be for the purpose set forth.

5. A gun-sight comprising two main members one of which is dotted longitudinally and the other of which is of a disc and shape to telescope into said dot, and means for approximating the arms of the larger member against the side face of the smaller member for the purpose set forth; combined with a base-plate on which the lower end of the larger member is pivotally supported, and a sight proper at the upper end of the smaller member.

696,943. FARM-GATE. ARTHUR R. CLAYTON, Dover, Mo. Filed Aug. 31, 1901. Serial No. 74,000. (No model.)

Claim.—1. The combination with a swinging gate having an upwardly-extended rear standard having an opening in its upper end and a central standard projecting above the top of the gate, of a weighted lever comprising parallel bars pivotally secured to the central standard and extending on opposite sides of the rear standard, a key in the opening of the said rear standard adapted to bear upon the upper side of the lever, a rod depending from said lever through guides on the gate-post, a bracket secured to the post on which the rod rests and a hinge connecting the gate and post which permits vertical movement of the gate.

2. The combination with a swinging gate having an upwardly-extended rear standard having an opening in its upper end, and a fixed central standard projecting above the top of the gate, of a weighted lever comprising parallel bars pivotally secured to the central standard and extending on opposite sides of the rear standard, a key in the opening of the said rear standard adapted to bear upon the upper side of the lever, a bracket secured to the post, a rod mounted in guides on the gate-post and having its lower end resting on the said bracket and pivotally supporting in its upper end the said lever and a hinge-connection between the lower end of the gate and the post, which permits of a vertical movement of the gate.

696,944. MECHANISM FOR OPERATING VIBRATING CHUQUER. HARRY COOPER, Selma, Ala., assignor of one-half to George W. Ballard, Selma, Ala. Filed Aug. 24, 1901. Serial No. 73,122. (No model.)

Claim.—The mechanism for vibrating a choker-body herein described, comprising a motor-spring, a gear on the shaft of a motor-spring, a shaft,

a pinion on the shaft in mesh with the motor-gear, a large gear-wheel on the shaft of the pinion, a pinion in mesh with the large gear-wheel and carrying a crank-arm, a piston connected to the crank, a rocking beam pivotally supported and having its lower end connected to the end of the piston, and a pull-rod having its outer end connected to the upper end of the rocking beam and its other end connected to the drum-body.

686,945. GRINDING OR POLISHING MACHINE. ADAM CHOSER, Fitchburg, Mass. Filed Jan. 10, 1901. Serial No. 43,728. (No model.)

Claim.—1. In a grinding-machine, a reciprocating platen or work-holder, means to reciprocate the same, a swing-arm carrying a polishing-wheel, said swing-arm comprising a vertical member suspended from a driving-shaft and having a shaft journaled in its lower end, a horizontal member pivotally mounted at one end on said last-mentioned shaft and carrying at its other end the polishing or abrading wheel, and pulleys on the end of the shaft connecting the horizontal and vertical members and on the outside of said members for transmitting motion from the driving-shaft to the polishing-wheel.

2. In a grinding-machine, a frame, a reciprocating platen or work-holder thereon, combined with a swing-arm for supporting the polishing-wheel, said arm comprising a vertical member suspended from a driving-shaft and having a yoke at its lower end, a shaft mounted therein, a horizontal member pivotally mounted at one end on said shaft and between the arms of the yoke, and having a shaft journaled in its other end so

which is mounted a polishing or abrading wheel, the shaft connecting the horizontal and vertical members having at each end outside the arms of the yoke a pulley, and belts connecting one of said pulleys with the driving-shaft, and the other pulley with the counter-shaft.

3. In a grinding-machine, a reciprocating platen or work-holder, means to reciprocate the same, combined with a jointed swing-arm suspended from a driving-shaft and carrying at its free end a shaft on which is mounted an abrading-wheel, pulleys located at the joint of said arm and outside of the same, both cooperating therewith for transmitting motion from the driving-shaft to the abrading-wheel, the construction being such that the belts may be removed or replaced without disconnecting the swing-arm combined with counterbalancing means for said swing-arm.

4. In a grinding-machine, a reciprocating platen or work-holder, means to reciprocate the same, combined with a swing-arm supported from a driving-shaft and carrying at its free end an abrading-wheel, said swing-arm comprising a vertical member and a horizontal member, one of said members having a yoke at one end and the other member having a head fitted between the arms of the yoke, a shaft passing through said head and the arms of the yoke and serving to pivotally connect said members, a pulley on each end of said shaft outside of the arms of the yoke, and belts connecting said pulleys with the counter-shaft and abrading-wheel, respectively, the said vertical member of the swing-arm having a swivel connection between its ends, whereby the abrading-wheel may be given a circular motion.

5. In a grinding-machine, a frame, a reciprocating platen or work-holder thereon, means to reciprocate the same, combined with a swing-arm supported from a driving-shaft and carrying at its free end an abrading-wheel, said swing-arm comprising a vertical member, a horizontal member, and a shaft connecting said members on each end of which is mounted a pulley outside of said members, belts connecting said pulleys with the counter-shaft and abrading-wheel, a bumper on the horizontal member, and stop-bars on the frame cooperating therewith to limit the horizontal movement of the swing-arm.

6. In a grinding-machine, a frame having guideways, a platen or work-holder supported thereon for reciprocating movement, and having connected therewith a rack, a gear engaging said rack, a shaft connected with said gear, and reversing mechanism for said shaft, means operated by the platen as it reaches the end of its stroke to operate said reversing mechanism combined with a jointed swing-arm supported from a driving-shaft and carrying at one end an abrading-wheel, pulleys located at the joint of said swing-arm and on the outside of said arm, and belts transmitting motion from the driving-shaft to the abrading-wheel.

7. In a grinding-machine, a frame having guideways, a platen or work-holder supported thereon for reciprocating movement, and having connected therewith a rack, a gear engaging said rack, a shaft connected with said gear for rotating the same, and reversing mechanism for the shaft comprising a sliding rod having adjustable cushioned stops thereon, and an arm on the platen slidably engaging said rod whereby the reversing mechanism is operated by the platen, combined with a jointed swing-arm suspended from a driving-shaft, and carrying at its free end an abrading-wheel, transmitting-pulleys located at the joint thereof, and on the outside of said arm, and belts connecting said pulleys with the abrading-wheel and driving-shaft respectively.

8. In a grinding-machine, a frame having guideways, a platen or work-holder supported thereon for reciprocating movement, and having connected therewith a rack, a gear engaging said rack, a shaft connected with said gear, reversing mechanism for said shaft, means operated by the platen as it reaches the end of its stroke to operate said reversing mechanism, combined with a jointed swing-arm supported from a driving-shaft and carrying at its free end an abrading-wheel, transmitting-pulleys located at the joint of said arm and on the outside thereof, belts connecting said pulleys with the driving-shaft and abrading-wheel respectively, a bumper on said swing-arm, and adjustable stop-bars on the frame cooperating therewith, to limit the longitudinal movement of said arm.

9. In a grinding-machine, a reciprocating platen or work-holder, a jointed swing-arm suspended from a shaft and carrying at its free end a yoke, a shaft journaled therein having an abrading-wheel thereon, means for driving said shaft from the driving-shaft, and adjusting device in the said yoke and engaging the ends of the abrading-wheel shaft, whereby the said shaft may be held against longitudinal movement in its bearings.

10. In a grinding-machine, a reciprocating platen or work-holder, a jointed swing-arm suspended from a shaft, and carrying at one end a yoke, a shaft having an abrading-wheel thereon mounted in said yoke with the wheel between the arms of the yoke, handles adjustably secured in the said yoke and in line with the abrading-wheel shaft, and bearing against the ends of said shaft, whereby the shaft may be adjusted for longitudinal wear, and means for transmitting motion from the drive-shaft to the abrading-wheel shaft.

11. In an apparatus of the class described, a reciprocating platen or work-holder, means to reciprocate the same, a swing-arm suspended

over the work-holder and comprising a vertical member mounted to swing about a horizontal axis, a horizontal member pivoted in the lower end of said vertical member, said horizontal member being mounted to swing about both a horizontal and a vertical axis, a polishing or abrading wheel supported on the free end of said horizontal member, means to rotate said wheel and steps cooperating with the horizontal arm to limit its movement in any direction.

12. In a grinding-machine, a reciprocating platen or work-holder, means to reciprocate the same, a swing-arm suspended over the work-holder and comprising a vertical member and a horizontal member pivoted together, a polishing or abrading wheel carried by said horizontal member, means to rotate said wheel and steps to limit the movement of the swing-arm in a direction transverse to the movement of the platen.

686,946. CONTROLLING ELECTRIC MOTORS. MAXWELL W. DAY, Schenectady, N. Y., assignor to the General Electric Company, a Corporation of New York. Filed July 12, 1900. Serial No. 723,685. (No model.)

Claim.—1. A system of control for electric motors, comprising a plurality of distributing-wires carrying different electric potentials, motors supplied thereby, controlling devices for imposing different potentials on the motors, connections with the motors whereby at normal speeds they are distributed between different pairs of wires, and an equalizing device for maintaining an electrical balance in the system when some of the motors are connected for high speeds.

2. A system of control for electric motors, comprising three distributing-wires having different electric potentials, motors connected at normal speeds between different pairs of wires, means for connecting the several motors between the high-potential wire and an auxiliary generator of less capacity than the main generator, connected between the low-potential wires and adapted to absorb or yield energy according to the distribution of load on the system.

3. A system of motor control comprising a three-wire distributing system, motors connected between the wires so as to equally divide the load on the two sides of the system at normal motor speeds, switches for connecting any motor between the high-potential wire, and an auxiliary generator between the central or compensating wire and an outside wire.

4. A system of motor control comprising a three-wire distributing system, motors connected between the wires to equally divide the load on the two sides of the system at normal motor speeds, switches for connecting any motor with the high-potential wire, and an auxiliary compensating generator between a pair of low-potential wires belted or otherwise connected to the main generator and having a fractional electromotive force relatively to that of said main generator.

5. A system of motor control comprising a three-wire distributing system, motors connected between the wires to equally divide the load on the two sides of the system at normal motor speeds, switches for connecting any motor with the high-potential wire, and an auxiliary compensating generator between a pair of low-potential wires having a frac-

tional capacity and fractional electromotive force relatively to that of the main generator.

686,947. SYSTEM OF OPERATING FANS BY POWER FOR VENTILATING PARHUSSES-GARA. ROBERT H. DUNN, East Orange, N. J. Filed Sep. 18, 1900. Serial No. 34,717. (No model.)

Claim.—1. In a system of our ventilation, the combination of a steam-train-pipe system, a connection between the steam-train-pipe system and a steam supply, an air-compressor adapted to supply air to the steam-train-pipe system, a pneumatic fan-motor and a connection between the steam-train-pipe system and the pneumatic fan-motor, with means for opening and closing the said connection to prevent steam from flowing to the pneumatic motor when the steam train-pipe is employed for heating purposes.

2. The combination of a train-pipe system, a pneumatic fan-motor, a connection between the said motor and the train-pipe system, an air-storage reservoir and a gas-storage reservoir, a valved pipe connection between the air-storage reservoir and the gas-storage reservoir and a valved pipe connection between the air-storage reservoir and the train-pipe.

3. The combination of a train-pipe arranged for connection either with a steam-supply or with a supply of compressed air, with pneumatic fan-motors located on cars, a valved connection from the train-pipe to said pneumatic fan-motors, and another valved connection from said train-pipe to a car-heating system, whereby the train-pipe may be used either for supplying steam to the heating system only, or for supplying compressed air to the pneumatic fan-motors only.

686,948. ACETYLENE-GAS GENERATOR. EDWARD J. BOLAN, Philadelphia, Pa., assignor, by mesne assignments, to the Acetylene House Lighting Company, a Corporation of West Virginia. Filed Mar. 19, 1901. Serial No. 684,903. (No model.)

Claim.—1. In an apparatus for the production of acetylene gas, the combination with the generating-chamber, of a carbide-holder consisting of an open-work cage movably supported within the chamber, a water-supply pipe extending within the chamber to discharge on a limited portion of the carbide, and means operated by variations of the gas-pressure to move the cage and present different portions of the carbide to the water-discharge, substantially as set forth.

2. In an apparatus for the production of acetylene gas, the combination with the generating-chamber, of a carbide-holder consisting of an open-work cage pivotally supported within the chamber, means to discharge water on a limited portion of the cage-surface, and means oper-

ated by variations in the gas-pressure to move the cage and thereby change the position of the carbid within the cage, substantially as set forth.

2. The combination with the carbid-holder of an acetylene-gas generator and mechanism for automatically agitating the mass of a diaphragm adapted to be raised by the gas-pressure and to thereby automatically agitate the carbid-holder, and the weighted lever adapted to return the diaphragm to position when the gas-pressure is decreased, substantially as described.

4. In combination with a rotatable drum or cylinder for holding calcium carbid in a gas-generator, the gas-chamber, the gas-pipe leading from said chamber, a chamber having a flexible diaphragm in connection with the gas-outlet pipe, a rod attached to the diaphragm and extended through the top plate of the diaphragm-chamber, a ratchet-wheel upon the shaft of the drum or cylinder and connected substantially as described between said diaphragm and ratchet-wheel whereby an upward movement of the diaphragm will cause to partially rotate the drum.

5. The combination with a rotatable drum or cylinder for holding calcium carbid, the gas-chamber of a generator, the gas-pipe, the mechanism actuated by pressure of gas within the pipe, for effecting a partial rotation of the carbid-holder, and a weight for returning the mechanism actuated by the pressure of gas to its original position when the gas-pressure diminishes, substantially as described and for the purpose specified.

6. In a generator for producing acetylene gas, the combination of a chamber within which the gas is generated, a liquid-receptacle, and a rotary carbid-holder adapted to bring successive portions of the carbid into communication with the liquid-supply, and a shifting mechanism automatically controlled by the gas generated for rotating the carbid-holder.

7. In a generator for producing acetylene gas, the combination of a chamber within which the gas is generated, a liquid-receptacle, a rotary carbid-holder adapted to bring successive portions of the carbid into communication with the liquid-supply, and a shifting mechanism automatically controlled by the gas generated for rotating the carbid-holder.

8. In an acetylene-generator, the combination of a liquid-holder, a carbid-holder, and a motor mechanism automatically controlled by the pressure of the gas generated for moving the carbid-holder, whereby different portions of the carbid are successively subjected to the action of the liquid.

9. In a generator for producing acetylene gas, the combination of a liquid-receptacle provided with an outlet-passage, a carbid-holder, and an component automatically controlled by the pressure of the gas generated for moving one of said parts relatively to the other whereby different portions of the carbid are successively subjected to the action of the liquid.

10. In an apparatus for the production and storage of acetylene gas, a generator comprising a chamber, in combination with a rotatable perforated or open-work cylinder pivoted thereto and adapted to contain calcium carbid, a tube adapted to convey water to the carbid within the cylinder, and means for rotating the cylinder by the action of the gas generated.

696,949. METHOD OF MAKING THIN BOILING STARCH. CHAS. H. DUNN, New York, N. Y. Filed May 24, 1901. Serial No. 81,738. (No specimen.)

Claim.—The method of making a thin boiling or modified starch consisting in treating the starch, mixed with water, with acid while the starch is held in a free flowing state of suspension and maintained at a degree of temperature as high as practicable without breaking down the

starch granules and subsequently, while the mixture is held in suspension, neutralizing the acid and finally drying.

696,950. ROUTING OR ENGRAVING MACHINE. WILLIAM S. RAYOR, Sag Harbor, N. Y. Filed Nov. 28, 1900. Renewed Nov. 1, 1901. Serial No. 58,399. (No model.)

Claim.—1. In an engraving-machine or the like, a freely-pivoted tool-carrier beam, the tool-carrier arm of said beam being free to be lifted from its working position and falling freely toward said position, and a spring interposed between some portion of said beam and the frame of the machine and operatively engaging both of said parts just about as the beam reaches its working position but out of operative engagement with one of said parts when the beam is lifted, thereby providing a cushion for said beam, substantially as described.

2. In an engraving-machine or the like, a freely-pivoted tool-carrier beam, the tool-carrier arm of said beam being free to be lifted from its working position and falling freely toward said position, a spring be-

tween some portion of said beam and the frame of the machine and operatively engaging both of said parts just about as the beam reaches its working position but out of operative engagement with one of said parts when the beam is lifted, thereby providing a cushion for said beam, said spring being attached to one of said parts, and a cut-screw attached to the other of said parts and engaging said spring as the said beam is about to reach its working position; substantially as described.

3. In a routing-machine, an upright support provided with vertical ways in combination with means mounted in said ways to support and adjust the routing-tool, and a supporting-table or right-angular frame mounted in said ways to be adjusted and secured therein, said table provided with vertical ways in combination with a supporting-bracket mounted in said ways to be adjusted and secured therein, and a lever suspended from said bracket and means to secure said parts together or to adjust the same with reference to each other, substantially as described.

4. In an engraving or routing machine, a suspended lever and adjustable connection pivotally connected and mounted as follows: a bifurcated bracket carrying center-bearing points in its arms, said bracket being adjustably mounted in vertical ways in a supporting-frame, a ring having oppositely-disposed center bearings and oppositely-disposed center points, a vertical lever provided with a collar adjustably secured thereto and having oppositely-disposed center bearings, the ring being mounted between the arms of the bracket and the collar within the ring in combination with a link having a bifurcated end, with center-bearing points in the arms of said bifurcated end, a ring having oppositely-disposed center bearings and oppositely-disposed center-bearing points; a second collar adjustably secured to said vertical lever, said collar having oppositely-disposed center bearings, the ring being mounted between the arms of the link and the second collar within the ring, substantially as described.

5. In an engraving or routing machine, an adjustable suspended lever pivotally connected and mounted as follows: a bifurcated bracket carrying center-bearing points in its arms, said brackets being adjustably mounted in vertical ways in a supporting-frame, a ring having oppositely-disposed center bearings and oppositely-disposed center points, a vertical lever provided with a collar adjustably secured thereto and having oppositely-disposed center bearings, the ring being mounted between the arms of the bracket and the collar within the ring in combination with a link having a bifurcated end, with center-bearing points in the arms of said bifurcated end, a ring having oppositely-disposed center bearings and oppositely-disposed center-bearing points; a second collar adjustably secured to said vertical lever, said collar having oppositely-disposed center bearings, the ring being mounted between the arms of the link and the second collar within the ring, the link being pivotally connected at the other end with an engraving-table having a universal movement, and a vertical lever being pivotally connected to a tracer-stylus, substantially as described.

6. In an engraving or routing machine, a leverage system pivotally connected and mounted as follows: a bifurcated bracket carrying center-bearing points in its arms, said brackets being adjustably mounted in vertical ways in a supporting-frame, a ring having oppositely-disposed center bearings and oppositely-disposed center points, a vertical lever provided with a collar adjustably secured thereto and having oppositely-disposed center bearings, the ring being mounted between the arms of the bracket and the collar within the ring in combination with a link having a bifurcated end, with center-bearing points in the arms of said bifurcated end, a ring having oppositely-disposed center bearings and oppositely-disposed center-bearing points; a second collar adjustably secured to said vertical lever, said collar having oppositely-disposed center bearings, the ring being mounted between the arms of the link and the second collar within the ring, the link being pivotally connected at the other end with an engraving-table having a universal movement, and the vertical lever being pivotally connected to a tracer-stylus, the vertical lever being of two parts a sleeve and a shaft, the shaft being adjustable within the sleeve and means to secure the same therein, substantially as described.

696,951. ROUTING OR ENGRAVING MACHINE. WILLIAM S. RAYOR, Sag Harbor, N. Y. Filed Nov. 27, 1900. Renewed Nov. 28, 1901. Serial No. 58,398. (No model.)

Claim.—1. In a routing-machine, means to support and revolve a routing instrument, which consists of a cylindrical part, rotatably mounted, having a central screw-threaded aperture, a second cylindrical part, externally screw-threaded at one end to mate with the first cylindrical part, with means to lock said cylindrical parts together at any position within the limits of the helical movement, a third cylindrical part having an annular shoulder at one end, and having mounted within the same at the other end a central bearing, a second central bearing, adapted to fit into and be retained in the other end of said third cylinder, a shaft carrying two central bearings, adapted to fit in said central bearings, the third cylindrical part being run within the second cylindrical part, and means to secure a suitable routing instrument to said shaft, and means to revolve said shaft, substantially as described.

2. In a routing-machine, means to support and revolve a routing instrument, which consists of a cylindrical part having a central screw-threaded aperture and beveled ways in its base, the same being mounted on a bracket having a beveled tongue upon which said beveled ways may play, a second cylindrical part, externally screw-threaded to screw into the first cylindrical part, with means to lock said cylindrical parts together at any position within the limits of the helical movement, a third cylindrical part having an annular shoulder at one end, and having mounted within the same at the other end a central bearing, a second central bearing, adapted to fit into and be retained in the other end of said third cylinder, a shaft carrying two central bearings, adapted to fit in said central bearings, said shaft having also a tapering end on which the routing-instrument holder is journaled, the third cylindrical part being run within the second cylindrical part, and means to revolve said shaft, substantially as described.

3. In an engraving or routing machine, an engraving-table adjustably mounted to have a universal movement, a link pivotally connected to said table by a universal joint, a suspended lever pivotally mounted on a bracket by a universal-joint system, the other end of the link being pivotally connected with the upper end of said suspended lever, a frame pivotally connected with the lower end of said suspended lever, and a rock-shaft journaled in said frame with a tracer secured to said shaft and a lever secured thereto also, said lever having at the other end a socket, a second bracket secured to said bracket and having at the other end a socket and a shaft with ball-heads at either end thereof, said heads being mounted in said sockets, substantially as described.

4. In an engraving or routing machine, a leverage system pivotally connected and mounted as follows: a bracket with a head having a frame mounted on said head with center-bearing points, a collar having center bearings and adjustably mounted on said frame; a bifurcated vertical lever hinged to said collar by center bearings, a plate adjustably mounted on said vertical lever and having center bearings, and a link hinged to said plate by center bearings, said link being pivotally connected at the other end to an engraving-table adjustably mounted to have a universal movement; the lower end of said vertical lever being bifurcated, a frame pivotally mounted within said last-mentioned bifurcated arm, a rock-shaft journaled within said frame with a tracer-point secured to said rock-shaft, a rod secured to said rock-shaft at one end, and having a socket at the other end, a second bracket secured to said bracket, with a socket at the end of the second bracket, a shaft having ball-bearing heads at either end thereof mounted one in each of said sockets, substantially as described.

5. In an engraving-machine, a leverage system pivotally connected and mounted as follows: a bracket, a frame pivoted to the head of said bracket, a collar adjustably mounted on said frame, a vertical lever bifurcated at its lower end, and suspended from and pivotally connected to said collar whereby through the adjustment of the collar on the frame, the said connections of the vertical lever may be brought into the same plane or moved out of such plane, an engraving-table mounted to have a universal movement, a plate adjustably mounted on the vertical lever, and connected to one end of the lever, a link pivotally connected at one end by right-angular universal-jointed connections to said engraving-table and connected at the other to said plate, a frame connected to the other

end of the suspended lever, a rock-shaft journaled within said frame, a tracer mounted to said rock-shaft, an arm secured to said rock-shaft at one end and having a socket at the other end, a second bracket secured to said first-named bracket at one end and having a socket at the other end and a rod having ball-bearings ends and having in said sockets, substantially as described.

6. In an engraving-machine, a tracer mounted on a rock-shaft, means connecting the rock-shaft to the work-table and means maintaining said tracer in a vertical position by rocking said shaft relatively to the connecting means, substantially as described.

7. In an engraving-machine the combination of a suspended lever, a tracer mounted on a rock-shaft journaled at one end of the suspended lever, connection to a work-table, and means maintaining the tracer in a vertical position by rocking the shaft relatively to the connecting means, substantially as described.

8. In an engraving-machine, a lever suspended from a suitable bracket, a guide-arm frame hinged to the lower end of the suspended lever and a rock-shaft journaled in said frame, said rock-shaft carrying at one end a tracer and connected at the other end with a rock-arm, said rock-arm having a socket at one end, a second bracket secured to said first-named bracket at one end and having a socket at the other end, a rod having a knob at each end journaled in said sockets, the parts being mounted and adjusted, substantially as described.

696,953. ENGRAVING-MACHINE. WILLIAM S. HAYES, JR., Inventor. Filed Nov. 22, 1899. Renewed Jan. 26, 1902. Serial No. 91,867. (No model.)

Claim.—1. In an engraving-machine the combination with an engraving-table capable of universal movement, of a fixed graving-tool mounted to cooperate with said engraving-table, a suspended lever fulcrumed at two points, a pivoted link connected at one end to the suspended lever between the fulcrum-points and at the other end to the engraving-table, and a tracer carried by said suspended lever.

2. In an engraving-machine the combination with an engraving-table capable of universal movement of a fixed graving-tool mounted to cooperate with said engraving-table, of a suspended lever fulcrumed at two points, said fulcrum-points being relatively adjustable, a pivoted link connected at one end to the suspended lever between the fulcrum-points and at the other to the engraving-table, and a tracer carried by said suspended lever.

3. In an engraving-machine the combination with a stationary support, a plate mounted thereon to move in one direction, and an engraving-table mounted on said plate to move at right angles thereto, of a fixed graving-tool mounted to cooperate with said engraving-table, a suspended lever fulcrumed at two points, a pivoted link connected at one end to the suspended lever between the fulcrum-points and at the other to the engraving-table, and a tracer carried by said suspended lever.

4. In an engraving-machine the combination with a stationary support, a plate mounted thereon to move in one direction and an engraving-

table mounted on said plate to move at right angles thereto, of a fixed graving-tool mounted to cooperate with said engraving-table, a suspended lever fulcrumed at two points, said fulcrum-points being relatively adjustable, a pivoted link connected at one end to the suspended lever between the fulcrum-points and at the other end to the engraving-table, and a tracer carried by said suspended lever.

5. In an engraving-machine the combination of an engraving-table mounted on a series of balls running in grooves relatively at right angles, a plurality of tools mounted to cooperate with said engraving-table, a suspended lever fulcrumed at two points carrying a tracer and a link connecting the suspended lever and the engraving-table, said link being connected to the suspended lever between the fulcrum-points, substantially as described.

6. In an engraving-machine the combination of an engraving-table mounted on a series of balls running in grooves relatively at right angles, a plurality of tools mounted to cooperate with said engraving-table, a suspended lever fulcrumed at two points, said fulcrum-points being relatively adjustable, said suspended lever carrying a tracer and a link connecting the suspended lever and the engraving-table, said link being connected to the suspended lever between the fulcrum-points.

7. In an engraving-machine the combination of an engraving-table mounted on a series of balls running in grooves relatively at right angles, a plurality of tools mounted to cooperate with said engraving-table, a suspended lever carrying a tracer and provided with adjustable fulcrum-points and a link connecting the lever and the engraving-table, said link being connected to the suspended lever between the fulcrum-points substantially as described.

8. In an engraving-machine, a supporting-bracket, a plate mounted thereon by means of a system of balls running in grooves on said bracket and adapted to move in one direction, an engraving-table mounted on said plate by means of a system of balls running in grooves on said plate and adapted to move at right angles to the movement of the plate, a tool cooperating with the engraving-table, a tracer connected with a suspended lever, said lever having relatively adjustable fulcrums and a link connecting said lever and the engraving-table, said link being connected to the suspended lever between the fulcrum-points substantially as described.

9. In an engraving-machine the combination with an engraving-table having on its under side ways, a plate with ways on its upper side and ways on its under side, and a suitable support for said plate and table also having ways, the ways in the support and the under side of the plate being parallel and the ways in the upper side of the plate and the under side of the table being parallel, the ways between the table and the plate being at right angles to the ways between the plate and the support, ball-bearings interposed in each way, of an engraving-tool mounted to cooperate with the engraving-table, a suspended lever carrying a tracer, said lever having relatively adjustable fulcrums and a link connecting said lever to said engraving-table, said link being connected to the suspended lever between the fulcrum-points, substantially as described.

10. A lever and connection mounted as follows: a bracket with a head having center bearings, a frame mounted on said head with center-bearing points, a collar having center bearings adjustably mounted on said frame, a bifurcated suspended lever connected to said collar by center bearings a plate adjustably mounted on said suspended lever and having center bearings, and a link connected to said plate by center bearings, substantially as described.

11. In an engraving-machine a suspended lever fulcrumed at two points, and connected between said fulcrums to a universally-movable engraving-table, and connected at the free end to a tracer-point, with means to adjust and change the points of fulcrum with reference to each other, substantially as described.

12. In an engraving-machine, a vertical lever bifurcated at both ends with center-bearing points in each bifurcation and dots in the upper bifurcated arm, a supporting-bracket with a head and bearings in the head, a frame carrying two center-bearing points pivoted on the head of the bracket, an adjustable collar having bearings, mounted on the frame, a plate adjustably secured to the upper bifurcated end of said lever in said dot, said plate having bearings, a link having two bifurcated ends, one end being pivotally connected to said plate, and the other end to a block, a bifurcated frame pivotally connected to said block at right angles to said link connective to the same block, and said frame being connected to an adjustable engraving-table; an arm pivotally connected to the lower bifurcated end of said suspended lever, within said bifurcation, said arm also carrying a tracer-point at the other end thereof, substantially as described.

13. In an engraving-machine a vertical lever and connection joined to move in right-angular planes, and forming together a universal-joint connection, said lever connected near one end with an engraving-table, mounted to have a universal movement, and connected at the other end to a tracer, a bracket having a head, and having a frame pivoted to said head, with an adjustable collar mounted on said frame to which is hinged

one end of the vertical lever, so that by the adjustment of the collar on the frame, the position of fulcrum of the suspended lever may be brought into or away from the plane of the bracket-head-joint connection; a plate pivotally joined to the lever by a link, said link being adjustably mounted on the vertical lever, so that the plane of its jointed movement may be brought into or out of the plane of the movement of the vertical lever in both right-angular directions, and so that it may be adjusted with reference to either or both of the axes, substantially as described.

14. In an engraving-machine the combination with a pattern-table, a graving-tool and a carriage on which said tool is mounted, both said table and carriage being suitably mounted to move in parallel ways, a screw and gear connecting said table and carriage to move the carriage in commensure with the movement of the table with a degree of movement proportional to the difference between the size of the original work to be reproduced and the reproduced work.

15. In an engraving-machine a pattern-table and a carriage on which the graving-tool is mounted, both said table and carriage being mounted to move in ways in combination with a shaft suitably journaled and having thereon a screw-thread and at one end a beveled gear, a rack on the under side of the table, a driving-shaft suitably mounted carrying a pinion engaging said rack and a beveled gear; a train of shafting and beveled gears connecting the beveled gear of the screw-shaft and that of the driving-shaft, and means to revolve the driving-shaft, and a screw-threaded bracket secured to the carriage and engaging the screw-thread of the screw-threaded shaft, substantially as described.

16. In an engraving-machine a pattern-table provided with means to move the same, a graving-tool carriage suitably mounted to move in ways parallel with the movement of the pattern-table, and means to move said carriage in commensure with the movement of the table according to the degree of reduction required in reducing the matter traced to the size of the matter to be reproduced, said carriage being provided on its upper surface with dovetailed ways adapted to receive the dovetailed tongues of suitable supporting-blocks, and means to fix the said supporting-blocks in said ways; a supporting-arm pivotally connected with each of said blocks at one end and carrying the graving-tool at the other end, said arms projecting concentric to the axis of their pivotal mounting, substantially as described.

17. In an engraving-machine, a carriage suitably mounted in ways, and a pattern-table suitably mounted, both said table and carriage having a parallel motion, and means to move the same together, the degree of the movement of the carriage being dependent upon the degree of reduction from the work traced to the size of the work to be reproduced; beveled grooves in said carriage adapted to receive blades having beveled tongues; set-screws to secure said blades in the carriage; center bearings in said blocks; arms adapted to carry the graving-tool at one end and be pivotally secured to said blocks at the other end by center bearings, the arms extending from the blocks at an angle to the plane of the axis of their journal-bearings; a shaft suitably mounted in journal-bearings; said journal-bearings being concentric to the axis of said shaft, and said shaft lying beneath the arms supporting the graving-tool in such relation that when the shafts are rocked, moving concentric to their axis they will lift the arms carrying the graving instruments, and raise the graving instruments off of the engraving-table; levers secured to said shaft, and a connecting-rod adapted to depress said lever to rock said shaft, substantially as described.

18. In an engraving-machine an engraving-table suitably mounted to have a universal movement in a horizontal plane, a link pivotally connected at one end to said table by a universal joint, a suspended lever having adjustable fulcrums mounted on a bracket by a universal-joint system, the other end of the link being pivotally connected with the upper end of said suspended lever between said fulcrums; a guide-arm pivotally connected to the lower end of said suspended lever at one end thereof, and carrying at the other end a tracer-point, substantially as described.

696,958. TRANSFORMER-CORE. AUGUST R. BYRNE, LYNN, ILL., assignor to General Electric Company, a Corporation of New York. Filed Mar. 6, 1901. Serial No. 49,003. (No model.)

Claim.—1. A laminated transformer-core which has two legs, each having the same number of laminations, which comprises a plurality of substantially U-shaped laminations, each of which has a long and a short leg; and also a plurality of end laminations for completing the magnetic circuit; said core being built up as that the long and short legs of the U-shaped laminations alternate in the respective core-legs; and the end laminations, the two coils being in position on the core-legs, being also alternated so that one coil of one lamination fills the space at the end of a short leg of a U-lamination of the first core-leg, the other coil of said end lamination abuts against the long leg of the same U-lamination in the second core-leg, one end of the said end lamination fills the space at the end of the short leg of the next U-lamination in the second core-leg, and so that the other end of the latter end lamination abuts against the long leg of the latter U-lamination in the first core-leg.

2. A transformer-core, which comprises a plurality of substantially U-shaped laminations, each of which has a long and a short leg; said laminations being assembled alternately to form two core-legs of the same thickness and the same number of laminations; and end laminations which complete the magnetic circuit.

3. A laminated transformer-core, which has two legs each having the same number of laminations and which comprises a plurality of substantially U-shaped laminations, each of which has a long and a short leg, said laminations being alternately reversed, so that each short leg is included between two long legs; and end laminations which complete the magnetic circuit.

4. A laminated transformer-core, which has two legs each having the same number of laminations, and which comprises a plurality of U-shaped laminations, each of which has a long and a short leg, said laminations being alternately reversed so that a short leg lies between two long legs and a long leg lies between two short legs, and laminations having a width substantially equal to the difference between the lengths of the long and short legs, one set of ends of which laminations fill the space in one core-leg between the long legs which lie on opposite sides of the short leg, and the other set of ends of which laminations abut against the sides of the long legs of the other core-leg.

5. A transformer-core, which comprises a plurality of substantially U-shaped laminations, each of which has a long leg and a short leg, said laminations being alternately reversed, so that each short leg is included between two long legs; and end laminations which alternate to fill the space between the long legs at the ends of the short legs and serve to complete the magnetic circuit.

6. A transformer-core, which comprises a plurality of substantially U-shaped laminations, each of which has a long and a short leg, certain of the laminations having the inner corners of the long legs cut away, and a core being built up first, with one or more laminations of one kind, next, laminations of the other kind, then laminations of the latter kind turned upside down, fourth, laminations of the first kind turned upside down and so on until the core is complete; and end laminations for completing the magnetic circuit, which laminations are inserted between the long legs of the U-shaped laminations as indicated by the cut-away corners.

7. A transformer-core, which is built of a plurality of substantially U-shaped laminations, each of which has a long and a short leg, each built-up core-leg being composed of long and short legs alternately arranged, all the long legs in both core-legs having guides at their ends which serve to indicate the proper space for the insertion of end laminations.

8. A transformer-core, which is built up of a plurality of substantially U-shaped laminations, of two kinds, both kinds of which have long and short legs, one of which kinds has the inner corners of the ends of the long legs cut away, the other of which kinds has the outer corners of the ends of the long legs cut away; and each leg of the core being composed of long and short legs alternately arranged, the two long legs which include a short leg belonging respectively to the said two kinds of laminations.

9. A transformer-core, which is built up of a plurality of substantially U-shaped laminations of two kinds, both of which kinds have long and short legs, one of which kinds has characteristic guides at the ends of the long legs, and the other of which kinds has different characteristic guides at the ends of its long legs; each leg of the core being composed of long and short legs alternately arranged, and the two long legs which include a short leg belonging respectively to the two kinds of laminations.

10. A transformer-core, which comprises a plurality of substantially U-shaped laminations, each of which has a long and short leg, certain of the laminations having the outer corners of the long legs cut away, certain other of the laminations having the inner corners of the long legs cut away, and the core being built up, first, with one or more laminations having an outer corner of the long legs cut away, second, with laminations having the inner corners of the long legs cut away; said long legs lying in the other leg of the core with respect to the first long leg; third, with laminations having the inner corners of the long legs cut away, but turned upside down so that the long

15. A transformer-core, which comprises a plurality of substantially U-shaped laminas, each having a long and a short leg, the difference between the lengths of the legs being equal to the width of the base of the laminas, and to one-half the distance between the legs, and said laminas for completing the magnetic circuit, the widths of which and laminar are equal to the difference between the lengths of the long and short legs of the U-shaped laminas.

3. In a filling-machine, the combination of opposite reservoirs, each provided with a valve-cage at its upper end having overflow-ports, a

2. In a filling-machine, the combination of appetite reservoirs, each provided with a valve-cage at its upper end having overflow-ports, a

valve in each case, upper and lower pipes connecting the lower ends of the reservoirs, a supply-pipe leading to the upper pipe, a discharge leading from the lower pipe, a two-way valve located in the upper pipe, an oppositely-disposed two-way valve located in the lower pipe, and means for simultaneously operating the four valves for the purpose described.

4. In a filling-machine, the combination of opposite reservoirs, a valved air-vent and a valved overflow at the upper end of each of the same, a discharge-valve for the reservoir, a valved inlet for the same, and means for positively alternately and reversely operating the valves of the overflow and outlet of the opposite reservoirs simultaneously with the operation of said discharge and inlet valves.

5. In a filling-machine, the combination of opposite reservoirs, an intermediate valve-case having an inlet-port communicating with each reservoir and with a discharge leading from each cylinder, oppositely-disposed two-way valves located in said case, intermeshing gears carried by the stems of said valves, an operating-handle on the lower stem and a gear on the upper stem, a valve-case on the upper end of each reservoir, air-vents in the same, overflow-ports also in said case, rotatable valves for the cases each having an air-port and overflow-port, the two being arranged at an angle to each other, gears on the inner ends of the stems of said valves, a vertical shaft, gears on the upper and lower ends of the same, said gears meshing with the gears of the upper valve-stems and with that of the lower inlet-valve, and tubes adapted to lead from a source of supply to the inlet-port and from the overflow-ports to said source of supply.

696,956. MAGAZINE TORPEDO-CASE. JOHN E. FOX, FOSTORIA, Ohio. Filed Aug. 31, 1901. Serial No. 73,916. (No model.)

Claim.—1. A device for exploding torpedoes or the like comprising a mortar, and a firing-plug mounted on the lower end of a case-body or the like, having a magazine with a lateral outlet in the plug, the said firing-plug being telescopically mounted in the mortar and freely movable as a plunger therein to and from contact with the bottom of the mortar, and the said parts coacting in their reciprocation to feed the torpedoes or the like singly from the outlet of the magazine into the mortar and explode them in succession.

2. A device for exploding torpedo-pellets comprising a mortar telescopically mounted on a firing-plug freely movable to and fro in the mortar to and from contact with the bottom of the mortar and having a top socket, and a case-body or the like secured by its lower end in the socket of the plug and having a longitudinal bore adapted to form a magazine extending from the lower end upward to an inlet and provided with a lateral outlet within the plug kept closed by the mortar, the mortar being provided with a lateral recess adapted to be brought into alignment with the outlet of the magazine by the inward and to be uncovered by the plug in the outward movement of the plug in the mortar or of the mortar on the plug.

3. In a torpedo-case, a case-body provided with a magazine in the lower end, formed by a longitudinal bore extending upward to an inlet; a firing-plug permanently mounted on the lower end of the body, having an aperture in the base of the plug opening into a cavity in the plug; a lateral opening from the cavity into the base of the magazine, forming an outlet therefor; a mortar mounted on the plug and movable telescopically thereon between stops, and having a stud portion extended and movable in the aperture and cavity of the plug, and adapted to close the opening therefrom to the magazine; a firing-chamber in the breach of the mortar adapted to be closed at the top by the plug; a firing-pin projecting from the end of the plug into the firing-chamber; a vent in the wall of the firing-chamber; and a lateral recess in the side of the stud within the mortar adapted to be brought into alignment with the outlet of the magazine by the inward and to be uncovered by the plug in the outward movement of the plug in the mortar or of the mortar on the plug.

4. In a torpedo-case the combination with a case-body having a central longitudinal bore extending from the lower end toward the top and provided with a side opening having a closure, adapted to form a magazine for the storage of torpedoes, of a firing-plug having a socket at the top adapting the plug to be permanently mounted on the lower end of the case-body, and provided with an aperture on one side through the bottom of the plug into the socket, and with a projecting firing-pin on the other; a cavity within the socket of the plug formed by a side cut in the end of the case-body; an opening from the base of the bore of the magazine into the cavity; a mortar mounted on the plug and movable telescopically thereon and having a stud extended and movable in the aperture and cavity of the plug, and adapted to close the opening from the cavity into the magazine; a vertical slot in the wall of the plug-socket opposite the cavity; a pin secured to the stud and projecting through the

slot, adapted to movably secure the mortar to the plug and limit their telescopic movement; a firing-chamber in the breach of the mortar, adapted to be closed at the top by the plug; a vent in the wall of the firing-chamber; a firing-pin projecting from the bottom of the plug into the firing-chamber adapted to touch the bottom of the chamber at the limit of its inward movement therein; and a recess in the side of the stud adapted to be brought into alignment with the opening in the magazine by pushing the plug into the mortar and into coincidence with the firing-chamber by withdrawing it, substantially as shown and described and for the purpose set forth.

696,957. FLAG-CASE. JOHN W. FREEMAN, ELGIN, ILL. Filed Feb. 2, 1902. Serial No. 4,603. (No model.)

Claim.—A case having a bore extending from a point near its handle portion throughout the remainder of its length, a staff of less diameter than the bore, and normally housed therein, two spaced collars or shoulders carried by the staff and snugly fitting the bore, the outer collar, when the staff is projected, operating to close the open end of the bore to prevent vibration of the staff therein, and the inner collar operating to prevent any vibratory motion of that portion of the staff within the bore, whereby breakage of the staff and splitting of the case is prevented, a spring-pressed trigger projecting within the bore and engaging the inner collar to hold the staff in retracted position, a spring interposed between the latter collar and the closed terminal of the bore, and a display device carried by the outer portion of the staff, substantially as and for the purpose specified.

696,958. INSULATOR FOR HIGH-POTENTIAL CURRENTS. RUDOLF GANZNER, MARCHBURG, near Griesbach, Austria-Hungary, assignor to Karlshofen Kautschuk-Industrie-Gesellschaft, Marchburg, near Griesbach, Bohemia, Austria-Hungary. Filed Jan. 12, 1902. Serial No. 20,005. (No model.)

Claim.—1. A high-potential electric insulator composed of a plurality of bells connected together at the points d and e and having an air-space c practically insulating the inner bell.

2. A high-potential electric insulator composed of a plurality of glazed bells glazed together at the shoulders d and e, and having an air-space or interstice c between them.

696,959. COTTON-SEED DOLLIER. JEFFERSON M. GARDNER, New London, Conn. Filed Jan. 12, 1902. Serial No. 42,794. (No model.)

Claim.—1. A cotton-seed-dolliering machine comprising a series of rows, a movable roll-bar arranged adjacent to the rows, a feed arranged

in the roll-box, a shaft having a gear thereon, a train of gears one of which is connected to the first-shaft, meshing with the gear on the shaft, the gear on the first-shaft being capable of lateral movement without disengaging it from the remainder of the train of gears, whereby the shaft and the first remain connected by the gears irrespective of the position of the roll-box, substantially as described.

2. A cotton-seed delinting machine comprising a series of saws, a movable roll-box arranged adjacent to the saws, a shaft arranged in the roll-box, means for driving the shaft comprising a train of gears, a casing for the gears having a movable portion, whereby movement of the roll-box without disengaging the gears is permitted substantially as described.

3. A cotton-seed delinter comprising a series of saws, a movable roll-box arranged adjacent to the saws, a shaft arranged in the roll-box, and means for driving the shaft comprising a belt, a belt-tightener mounted adjacent to the belt, and a connection between the belt-tightener and the roll-box, substantially as described.

4. A cotton-seed delinter comprising a series of saws, a movable roll-box arranged adjacent to the saws, a shaft arranged in the roll-box, a shaft arranged above the roll-box, a belt connecting the shaft and the shaft above the roll-box, gears connecting the latter shaft and the shaft, a belt-tightener, and a connection between the belt-tightener and the roll-box, substantially as described.

5. A cotton-seed delinter comprising a roll-box having a portion of its inner face movable, a feeder adjacent to the roll-box, means for imparting movement to the feeder comprising three friction-wheels the intermediate one being movable to bring it into and out of contact with the others, a bell-crank lever on which the movable friction-wheel is mounted, a link pivotally connected to the lower end of the bell-crank lever, and a connection rigidly connected at one end to the movable section and adjustably connected at its other end to the link, substantially as described.

696,960. SPARK ARRESTER AND EXHAUSTOR. ALBERT GARNER, Rockburg, Va. Filed May 21, 1901. Serial No. 62,601. (No model.)

Claim.—1. In a spark-arrester, the combination of a series of supporting-rods provided with means at their lower ends for securing them to a support, a draft-tube supported on the rods, and an inverted cone supported above the draft-tube and provided with numerous outward-extending pins.

2. In a spark-arrester for smoke-stacks, the combination of a series of rods provided with means for adjustably securing them to a support at their lower ends, a draft-tube supported on the rods intermediate their ends, an inverted cone attached to the upper ends of the rods above the draft-tube and provided with numerous outward-extending pins, and means for centering the apparatus in the smoke-stack consisting of a series of fingers attached to the inverted cone and extending upward and outward and adapted so as to bear movably against the interior of the stack.

696,961. HYDROCARBON-BURNER. LEVIN G. GRAMMEL, San Jose, Cal. Filed Oct. 11, 1901. Serial No. 78,337. (No model.)

Claim.—1. In a hydrocarbon-burner, the combination of oppositely-facing standards, lateral rotors carried by said standards, a sloping upper rotor supported on said standards and having partitions extending alternately from opposite sides thereof to form a tortuous conduit therein, an oil-pen between the standards, an oil-supply pipe connected to the upper end of the upper rotor, a pipe leading from the lower end of said rotor to the upper portion of one of the lateral rotors, a pipe leading from the lower portion of the lateral rotor to the upper portion of the opposite lateral rotor, a pipe leading from the lower end of the conduit in said lateral rotor below the oil-pen and then extending upwardly therethrough, a burner mounted on the end of said latter pipe, and a spreader standing on said oil-pen above said burner, and having upwardly-flaring sides to spread the flames against the sides of the rotors, substantially as described.

2. In a hydrocarbon-burner, the combination of oppositely-facing standards, lateral rotors carried by said standards having vertical partitions extending alternately from opposite sides thereof to form a tortuous conduit therein, an oil-pen between the standards, an oil-supply pipe connected to the upper end of the upper rotor, a pipe leading from the lower end of said rotor to the upper portion of one of the lateral rotors, a pipe leading from the lower portion of the lateral rotor to the upper portion of the opposite lateral rotor, a pipe leading from the lower end of the conduit in said lateral rotor below the oil-pen and then extending upwardly therethrough, an inverted-cup-shaped burner mounted on the end of said latter pipe, and a spreader standing on said oil-pen above said burner, and having upwardly-flaring sides to spread the flames against the sides of the rotors, substantially as described.

696,962. SHOT FOR FIREARMS. CLARENCE J. HANCOCK, Plymouth, Mich., assignor to C. J. Hamilton & Son, Plymouth, Mich., a Partnership. Original application filed May 13, 1901, Serial No. 66,907. Divided and this application filed Jan. 2, 1902. Serial No. 81,326. (No model.)

Claim.—1. In gun-construction, the combination of the barrel and the front sight consisting of a metal band surrounding the barrel with the free ends brought together and upstanding to form a sight, substantially as described.

2. The combination of the barrel and the front sight consisting of the metal bands surrounding the barrel with its free ends brought together to form the sight in combination with the reinforcing-piece, substantially as described.

696,968. ELECTRIC SWITCH. GERALD W. HART, West Hartford, Conn., assignor to the Hart Manufacturing Company, Hartford, Conn., a Corporation of New Jersey. Filed Nov. 18, 1901. Serial No. 68,980. (No model.)

Claim.—1. In a snap-switch, a tilting operating part, a stationary frame, a link connected to said operating part, a locking-pin carried by said link and guided by said frame, a contact-carrier, said pin being adapted to engage on opposite sides of said contact-carrier, and a spring, one end being engaged by the operating part and the other end engaging said contact-carrier.

2. A snap-switch comprising, a stationary frame, a pivoted operating part, a swinging contact-carrier pivoted concentrically with said operating part, a reciprocating locking device controlled by said operating part and adapted to engage on opposite sides of said contact-carrier, and a spring one end being engaged by said operating part the other end engaging said contact-carrier.

3. In a snap-switch, a tilting operating part, a stationary frame, a link connected to said operating part, a locking-pin carried by said link and guided by said frame, a contact-carrier, said pin being adapted to engage on opposite sides of said contact-carrier, a spring, one end being engaged by the operating part and the other end engaging said contact-carrier, and another spring for normally returning the operating part to its original position.

4. In a snap-switch, a tilting operating part, a stationary frame, a link connected to said operating part, a locking-pin carried by said link and guided by said frame, a contact-carrier, said pin being adapted to engage on opposite sides of said contact-carrier, a spring, one end being engaged by the operating part and the other end engaging said contact-carrier, and a stop for limiting the movement of said operating part.

696,964. TIE-PLATE. HERBERT H. HART, Chicago, Ill. Filed Nov. 1, 1901. Serial No. 66,763. (No model.)

Claim.—1. A tie-plate provided upon its upper surface with a plurality of grooves or depressions contracted at their inner ends and gradually widening toward the edge of the tie-plate, substantially as described.

2. A tie-plate provided upon its upper surface with a plurality of grooves or depressions, said grooves or depressions being contracted at their inner ends and gradually widening and deepening as they approach the edge of the tie-plate, substantially as described.

3. A tie-plate provided upon its under surface with a plurality of sharpened flanges adapted to enter the tie, and upon its upper surface with a plurality of grooves or depressions extending outward from the central portion of said tie-plate, said grooves being contracted at their inner ends and gradually widening as they approach the edge of the tie-plate, substantially as described.

4. A tie-plate provided upon its under surface with a plurality of sharpened flanges adapted to enter the tie, and upon its upper surface with a plurality of grooves or depressions extending outward from the central portion of said tie-plate, said grooves being contracted at their inner ends and gradually widening and deepening as they approach the edge of the tie-plate, substantially as described.

5. A tie-plate provided on its upper surface with two series of grooves or depressions, each series of grooves extending outward from the median line of said tie-plate, said grooves being contracted at their inner ends and gradually widening as they approach the edge of the tie-plate, substantially as described.

6. A tie-plate provided on its upper surface with two series of grooves or depressions, each series of grooves extending outward from the median line of said tie-plate, said grooves being contracted at their inner ends and gradually widening and deepening as they approach the edge of the tie-plate, substantially as described.

696,965. WICKING-FASTENER. WILLIAM H. HART, Jr., Philadelphia, Pa. Filed Nov. 18, 1901. Serial No. 68,487. (No model.)

Claim.—1. A wire wicking-fastener composed of two branches forming an upright diamond-shaped figure, the extensions of the upper sides of said diamond being bent upon themselves to constitute the upper securing member of the fastener, and the lower sides of said diamond being formed by the inner sides of two oppositely-disposed loops of which the wire of the inner side of each of said loops crosses under the wire of the outer side of each of said loops at the loop top of the end is bent downward and then bent upon itself to form the lower securing member of said fastener, substantially as described.

2. A wire wicking-fastener composed of two branches forming an upright diamond-shaped figure, the extensions of the upper sides of said diamond being bent upon themselves to constitute the upper securing member of the fastener, and the lower sides of said diamond being formed by the inner sides of two oppositely-disposed loops of which the wire of the inner side of each of said loops crosses under the wire of the outer side of each of said loops at the top of the loop and is then bent laterally into a triangular-shaped brace having a lower securing member for said fastener constituted by bending the lower inner end of said brace upon itself, substantially as described.

696,966. TOBACCO-STEERING ROLL. JOSEPH S. HAYES, Truxton, N. J. Filed Jan. 31, 1902. Serial No. 69,604. (No model.)

Claim.—1. A leaf-steering roll having a circumferential groove, and on each side of said groove inclined smooth portions of its periphery.

2. A leaf-steering roll having a circumferential groove, inclined smooth portions on each side of said groove, and circumferential cutting edges at the angles of said inclined portions.

3. A leaf-steering roll having a circumferential groove, and on each side of said groove two oppositely-inclined portions of its periphery.

4. The combination of two leaf-steering rolls one having circumferential grooves and abutting V-shaped channels, and the other similar circumferential grooves and abutting V-shaped ribs; the said ribs of one roll being received in the said channels of the other roll.

5. The combination of two leaf-steering rolls, each having its periphery so formed as that when said rolls are placed in juxtaposition leaf-like openings are produced between said rolls for the reception of the leaf to be steered.

6. The combination of two leaf-steering rolls each having a circumferential groove, the said groove extending to cross-section over an arc less than a semicircle; whereby when said rolls are placed in juxtaposition with their grooves opposite and corresponding, leaf-like openings are formed between said rolls.

7. The combination of the roll 3 having the grooves 5 and intermediate channels 10, 11, with the roll 4 having the grooves 7 and intermediate ribs 14, 15 adapted to enter said channels 10, 11.

696,967. TOBACCO-STEERING ROLL. JOSEPH S. HAYES, Truxton, N. J. Filed Jan. 31, 1902. Serial No. 69,605. (No model.)

Claim.—1. A half-stemming roll having circumferential grooves provided with concave cutting-surfaces, and alternating with said grooves pairs of circumferential cutting edges.

2. A half-stemming roll having circumferential grooves provided with concave cutting-surfaces and alternating with said grooves V-shaped channels, forming pairs of circumferential cutting edges.

3. A half-stemming roll having a circumferential groove provided with a concave cutting-surface formed of a multiplicity of small cutting projections, the said groove extending in cross-section over an arc less than a semicircle.

4. A half-stemming roll having a circumferential groove provided with a concave cutting-surface, and on each side of groove inclined smooth portions of its periphery.

5. A half-stemming roll having a circumferential groove provided with a concave cutting-surface and in each side of said groove two oppositely-inclined portions of its periphery.

6. The combination of the roll 3 having the grooves containing cutting-teeth 10 and intermediate channels 6 with the roll 4 having grooves 7 and cutting-teeth 10 and intermediate ribs 8 of a configuration adapted to fit in said channels 6, substantially as described.

7. The combination of the roll 3 having the grooves 5 containing cutting-teeth 10, V-shaped intermediate channels 6 with the roll 4 having grooves 7 and cutting-teeth 10 therein and the V-shaped ribs 8, substantially as described.

696,968. HAND TACKING-TOOL. ARTHUR HENRY, Manchester, N. H., assignor to Herbert R. Newton, Haverhill, Mass. Filed May 23, 1901. Serial No. 68,263. (No model.)

Claim.—1. A hand tacking-tool comprising a relatively fixed member and a movable member which is adapted to reciprocate with respect thereto and is provided with a tack-passage, a driving-plunger which is secured to said fixed member and is arranged in said passage, and a latch which is supported by said reciprocating member in said passage so that it may move freely in a predetermined path toward and away from said plunger, the path of movement of said latch being in the general direction of the path of the reciprocating member and being limited and arranged so that a portion thereof will be carried into such close proximity to the end of said plunger on one movement that a tack cannot pass therebetween and will be carried away therefrom on the opposite movement a sufficient distance to permit the passage of a tack therebetween.

2. A hand tacking-tool comprising a relatively fixed member and a movable member which is adapted to reciprocate relative thereto, and is provided with a tack-passage, a driving-plunger which is secured to said fixed member and is located in said passage, a latch which is arranged in said passage and is connected to said reciprocating member so that it may freely slide longitudinally of said passage, a projection on said latch which is so arranged that when said reciprocating member and latch are in their outermost positions said projection will be far enough beyond the end of said plunger to permit the passage of a tack therebetween, and when said

latch is moved inwardly with respect to said reciprocating member said projection will close the passage-way therebetween sufficiently to prevent the passage of a tack, and means for feeding the tacks into said passage one by one.

3. A hand tacking-tool comprising a relatively fixed member and a movable member which is adapted to reciprocate relative thereto, and is provided with a tack-passage, a driving-plunger which is secured to said fixed member and is located in said passage, a latch which is arranged in said passage and is connected to said reciprocating member so that it may freely slide longitudinally of said passage, a projection on said latch which is so arranged that when said reciprocating member and latch are in their outermost positions said projection will be far enough beyond the end of said plunger to permit the passage of a tack therebetween, and when said latch is moved inwardly with respect to said reciprocating member said projection will close the passage-way therebetween sufficiently to prevent the passage of a tack, a spring which is adapted to press the outer end of said latch toward the side of said passage below the end of said plunger, a stop for said spring which prevents it from pressing said latch into actual engagement with the side of said passage, and means for feeding the tacks one by one into said passage.

4. A hand tacking-tool comprising a relatively fixed member and a movable member which is adapted to reciprocate relative thereto, and is provided with a tack-passage, a driving-plunger which is secured to said fixed member and is located in said passage, a latch which is arranged in said passage and is connected to the reciprocating member so that it may freely slide longitudinally of said passage and swing laterally therein, a projection on the edge of said latch next the plunger at an intermediate position thereof, said projection being so arranged with respect to the end of said plunger when said reciprocating member and latch are in their outermost positions that a tack may pass between them, and will obstruct said passage of the tack when moved to its inner position with respect to said reciprocating member, means for swinging the edge of said latch below the plunger in close proximity to but not actually against the adjacent side of said passage, and means for feeding the tacks into said passage.

5. A hand tacking-tool comprising a relatively fixed member, a movable member which is adapted to reciprocate relative thereto and is provided with a tack-passage which extends to its outer end, a driving-plunger which is secured to said fixed member, and a latch which is arranged in said passage in front of said plunger, is connected to said movable member, and is adapted to reciprocate freely in a predetermined path, the path of said latch being in substantially the same direction as the path of said movable member and across the path of the tacks through said passage.

696,969. ELECTRIC SWITCH. EDWARD M. NEWLBY, Schenectady, N. Y., assignor to General Electric Company, a Corporation of New York. Filed Aug. 14, 1901. Serial No. 72,526. (No model.)

Claim.—1. The combination with a motor-starting switch, of an automatic circuit-breaker in circuit therewith, and connections with the

switch for temporarily raising the tripping-point of the circuit-breaker when the circuit is first closed.

2. The combination with a switch, of an automatic circuit-breaker in circuit therewith, and connections for temporarily increasing the tension of a calibrating-spring when the circuit is first closed.

3. The combination with a switch, of an automatic circuit-breaker in circuit therewith, and connections for temporarily increasing the resistance force of the tripping-arms when the circuit is first closed.

4. The combination with a switch, of an automatic circuit-breaker in circuit therewith, and mechanical connections between the switch and self-latching-spring of the circuit-breaker for temporarily increasing the tension of the latter during circuit-closure.

696,970. HARKNESS-BOOK. CHAS. W. HARKNESS, Baltimore, Md., assignor to Harkness Specialty Company, Limited, Baltimore, Md. Filed Jan. 27, 1902. Serial No. 91,682. (No model.)

Claim.—1. In a harkness-book, the combination of an engaging portion B, having inwardly and forwardly projecting portions f, e, g, arranged alternately thereon; a loop portion B' having forwardly-extending legs c, d, on either side of the said engaging portion to serve as guards, substantially as described.

2. In a harkness-book, the combination of an engaging portion B, having inwardly and forwardly projecting portions arranged alternately thereon; a loop portion B' having a forwardly-extending leg c to one side of the said engaging portion to serve as a guard, substantially as described.

3. In a harkness-book, the combination of an engaging portion; a loop portion B' having forwardly-extending legs c, d on either side of said engaging portion to serve as guards, substantially as described.

4. In a harkness-book, the combination of an engaging portion; a loop portion B' having a forwardly-extending leg c to one side of the said engaging portion to serve as a guard, substantially as described.

696,971. FIRING-VALVE FOR SUBMERSIBLE EXPLOSION-TURNER. JOHN F. HOLLAND, Newark, N. J. Filed July 27, 1901. Serial No. 68,262. (No model.)

Claim.—1. The combination with an explosion-tube and its firing-valve, of an automatic stop-valve located between the firing-valve and

the said tube to prevent the access of water to the firing-valve and its connections, substantially as set forth.

2. The combination with the explosion-tube, the casing of the firing-valve, and the coupling-piece connecting said casing with the explosion-tube, of the firing-valve and its piston, and the automatic stop-valve mounted in the said coupling-piece and opening toward the explosion-tube, substantially as set forth.

696,972. SUBMERSIBLE BOAT. JOHN F. HOLLAND, Newark, N. J. Filed Aug. 7, 1901. Serial No. 71,181. (No model.)

Claim.—1. A submersible boat or vessel having in it a closed tank containing a liquid hydrocarbon, means for charging and supplying the liquid from same, a ventilating-pipe extending from the upper part of said tank out through the shell or hull of the boat, a check-valve controlling said pipe and opening outwardly, and means for automatically controlling the admission of air to said tank from the interior of the boat to replace the liquid used.

2. A submersible boat or vessel having in it a closed tank containing a liquid hydrocarbon, means for charging and supplying the liquid from same, a ventilating-pipe extending from the upper part of said tank out through the shell or hull of the boat, a check-valve controlling said pipe and opening outwardly, said valve being situated exterior to the boat, and means for automatically controlling the admission of air to said tank from the interior of the boat to replace the liquid used.

3. A submersible boat or vessel having in it a closed tank containing a liquid hydrocarbon, means for discharging the accumulated gases and vapors from said tank exterior to the boat, a pipe from the interior of the boat for admitting air to said tank, and a check-valve controlling said pipe and opening inwardly, whereby the liquid consumed is replaced by air.

696,973. CLUTCH-OPERATING DEVICE. GEORGE L. BULLAN, Chicago, Ill., assignor to the Link Belt Machinery Company, Chicago, Ill., a Corporation of Illinois. Filed June 7, 1901. Serial No. 68,264. (No model.)

Claim.—1. In a controlling device, the combination of a movable part with pivoted bars on which it is supported, a fixed standard, short links pivoted together, and at their other ends respectively to the fixed standard and the pivoted bars, a rock-shaft, a lever to rock the same, an arm thereon, and a rod pivoted to the arm and to the short links at the points where they are pivoted together.

2. In a controlling device, the combination of a movable part with links pivoted together and at one end pivotedly connected with the movable part and at the other with a fixed part, and means for moving these links at the point where they are pivoted together to move the movable part, said means comprising two links pivoted together and one of them to a fixed part.

3. In a controlling device, the combination of a movable part with links pivoted together and at one end pivotally connected with the movable part and at the other with a fixed part, and means for moving these links at the point where they are pivoted together to move the movable part, said means comprising two links pivoted together and one of them to a fixed part, and arranged so as to form a straight line when the short links do not form a straight line.

4. In a controlling device, the combination of a movable part with means for moving it, comprising two sets of pivoted links adapted to successively form each set a straight line to lock the movable part at the limit of its excursion in either direction.

5. In a controlling device the combination of a movable part with links connected thereto adapted to form a straight line to lock the movable part in one direction, and a second set of links connected with the first, and adapted to form a straight line to lock the movable part at the limit of its excursion in the other direction.

6. In a controlling device the combination of a movable part with a rock-shaft and a connection from the rock-shaft to the movable part comprising two sets of links, adapted one to form a straight line to lock the movable part at the limit of its excursion in one direction, and the other to form a straight line to lock the movable part at the limit of its excursion in the other direction.

7. In a controlling device, the combination of a movable part with two systems of links, one connected with the movable part, the other with the first-mentioned system, and the two arranged so that they successively form straight lines, one to lock the movable part at the limit of its excursion in one direction, and the other to lock it at the limit of its excursion in the opposite direction.

8. In a controlling device, the combination of a movable part with a system of links connected therewith at one end and to a fixed point at the other end, and a second system of links connected at one end to a fixed point and at the other end to the first system of links intermediate between the two ends of each first system.

9. In a controlling device, the combination of a movable part with a system of links connected therewith at one end and to a fixed point at the other end, and a second system of links connected at one end to a fixed point and at the other end to the first system of links intermediate between the two ends of each first system, and means for varying the position of the second system of links to vary the position of the first system and thus move such movable part.

10. In a controlling device, the combination of a movable part with a system of links connected therewith at one end and to a fixed point at the other end, and a second system of links connected at one end to a fixed point and at the other end to the first system of links intermediate between the two ends of each first system, and means for varying the position of the second system of links to vary the position of the first system and thus move such movable part, each of said systems of links adapted in turn to form a straight line to lock the movable part at the limit of its excursion in either direction.

11. In a controlling device, the combination of a movable part with links pivoted together and at one end pivotally connected with the movable part and at the other with a fixed part, means for moving these links at the point where they are pivoted together to move the movable part, and an adjusting device associated with the means for moving the links so as to vary the excursion of the controlling device.

12. In a controlling device, the combination of a movable part with means for moving it, comprising two sets of pivoted links adapted to successively form each set a straight line to lock the movable part at the limit of its excursion in either direction and one of said sets of pivoted links adjustable in length to vary the motion of the controlling device.

13. In a controlling device, the combination of a movable part with a system of links connected therewith at one end and to a fixed point at the other end, and a second system of links connected at one end to a fixed point and at the other end to the first system of links intermediate between the two ends of each first system, said second system of links adjustable as to length to vary the excursion of the controlling device.

14. In a clutch-moving mechanism, the combination of a device to connect with the clutch, pivoted here on which it is supported, a rock-shaft and means for operating the same, and a connection from the rock-shaft to the bars, consisting of two sets of links.

15. In a clutch-moving mechanism, the combination of a device to connect with the clutch, pivoted here on which it is supported, a rock-shaft and means for operating the same, and a connection from the rock-shaft to the bars, consisting of two sets of links, one set substantially at right angles to the other and connected with each other at other the manner of toggle-bars.

16. In a clutch-moving mechanism, the combination of a device to connect with the clutch, pivoted here on which it is supported, a rock-shaft and means for operating the same, a connection from the rock-shaft to the bars, consisting of two sets of links, one set substantially at right

angles to the other and connected with each other at other the manner of toggle-bars, and an adjustable device associated with said links so as to vary the throw of the clutch-controlling part.

696,974. PEE-CUTTER. JOHN A. HOLMES, Mason City, Iowa. Filed Apr. 20, 1901. Serial No. 54,136. (No model.)

Claim.—A peg-foot, comprising a pair of levers pivoted together and extending rearwardly from the pivotal point substantially parallel to each other for some distance from said pivotal point and thence diverging upwardly, and provided at their free ends with loops or eyes, and provided at their forward ends with cutting-jaws which extend below the plane of the pivotal connection, said cutting-jaws having rounded under surfaces, the outer jaw moving upward and outward with relation to the inner jaw when opening, substantially as described.

696,975. PROPELLING AND BRAKE MECHANISM FOR VEHICLES. OMAR C. HOWEN, Cortland, N. Y., assignor to the Cortland Carriage Goods Company, Cortland, N. Y., a Corporation of New York. Filed Oct. 24, 1900. Serial No. 54,302. (No model.)

Claim.—1. In combination with a Weyde or like vehicle, a driving and braking device comprising a clutch member secured to the hub of the driven wheel; a second clutch member loose upon said hub; means for causing said second member to engage the companion member when half turned in a forward direction; a brake member rigidly secured to or carried by said hub; a sliding brake member laterally movable toward and from the first; a non-rotatable yoke or support in which the second brake member is swiveled; a locking device adapted to engage said second brake member and positively hold it against forward rotation while permitting it to turn freely backward; and means for pressing the brake members together and for relieving them of pressure, alternately and as desired.

2. In combination with a wheel or part to be driven, a driving-wheel having limited rotary play independent of the driven wheel, and provided

on its side face with inclines; a laterally-movable brake member; rollers interposed between said inclines and the laterally-movable brake member; a non-rotatable support for said member; a dog or pawl adapted to hold said member against forward rotation; and a second brake member rigidly secured to the wheel or part to be driven.

3. In combination with a wheel, and driving mechanism substantially such as described and shown, adapted to apply lateral pressure when moved in a backward direction; a brake, comprising a non-rotatable yoke or support, a friction member, swiveled therein; a sliding friction member carried by the driven wheel; and a pawl or detent adapted to engage and positively hold the swiveled friction member against forward rotation but to permit free backward rotation thereof.

4. In combination with yoke J and a rotatable clutch member swiveled therein and provided with a notch or notches; pawl or dog O adapted to engage in said notch or notches, and tapering in the direction of its movement, substantially as and for the purpose set forth.

5. In combination with a vehicle frame and wheel, a yoke J provided with a seat or means of tapering form, a pawl or dog O having a body of corresponding form; a rotatable brake member mounted in the yoke and adapted to be engaged by said pawl or dog; a brake member secured to and rotatable with the wheel; and means for pushing said brake members into braking contact, substantially as described.

6. In combination with a wheel, and a frame or support, yoke J having a cavity or pawl-out of decreasing width toward its lower end; a rotatable brake member seated therein and provided with notches in place with said pawl-out; a pawl or dog O, likewise of decreasing width toward its lower end and provided with a nose to engage in the notches of the rotatable member; whereby the dog is adapted to move radially inward and to engage said member when the latter turns in a direction to move the pawl downward, and to be lifted and moved radially outward by said member when turned in the reverse direction; and means substantially as described and shown for forcing the brake members into braking contact.

7. In combination with a brake member provided with a groove or depression, a cap or cover Q provided with a lip or flange q to enter the groove or depression, substantially as and for the purpose set forth.

696,976. CAR-ROOF. CURTIS M. JACOBSON, St. Louis, Mo. Filed Dec. 22, 1901. Serial No. 57,004. (No model.)

Claim.—1. In a car-roof, the combination with the sides of the car having respectively an outwardly-projecting top flange, of a carline made in one piece spanning the said sides, the said carline having a flat base bearing upon the said flanges, and having two upwardly-projecting side flanges directed outward at the top and formed thence respectively with a depending flange, a roof-sheet having a side flange adapted to engage between the said side flange and depending flange of the carline, and means for fixing the carline and roof-sheet to the said top flanges of the car, substantially as described.

2. In a car-roof, the combination with the sides of the car having respectively an inside top angle-plate, of a carline made in one piece spanning the said sides, the said carline having a flat base bearing upon the said plate, and having two upwardly-projecting side flanges directed outward at the top and formed thence respectively with a depending flange, a roof-sheet having a side flange adapted to engage between the said side flange and depending flange of the carline, and means for fixing the carline and roof-sheet to the said top plate of the car, substantially as described.

696,977. STOVEPIPE ATTACHMENT. JAMES JOY and JOHN H. DORRIS, Orléans, Mo. Filed Sept. 14, 1901. Serial No. 55,629. (No model.)

Claim.—1. A device of the character described comprising a clamp or strap thereto, a second clamp adjustably secured to the strap, and a tensioning device connecting the sides of the clamp opposite the strap.

2. The combination with an elbow, a pipe-section engaging the same, of a clamp applied to the elbow at the end furthest removed from the pipe-section and having a strap extending upwardly over the elbow and

a portion of the said section, the said strap being provided with a plurality of lugs, a second clamp on the pipe-section having adjustable engagement with the lugs on the strap, and an adjustable tie for connecting the two clamps.

3. A device of the class set forth comprising a strap provided with lugs at one extremity and a clamp at the opposite extremity, a second clamp having means for adjustably engaging the said lugs, and means for securing the terminals of the clamps, and an adjustable tie device for connecting the means securing the terminals of the clamps.

696,978. WAGON-ROD SUPPORT. PHILIP A. KIMBLE and JOHN E. KIMBLE, Chicago, Ill. Filed Aug. 17, 1901. Serial No. 72,622. (No model.)

Claim.—As an article of manufacture, a helical wire spring, a U-shaped bar at each end of the spring having its extremities bent outwardly into hook form and encircling the end convolutions of the spring and having a short web portion disposed within the end of the spring, two plates having perforations in their ends, each plate receiving the light of one of the bars in one of its perforations and said plates being passed in opposite directions through the spring, a chain engaged with the outer end perforation of one plate, a hook having a perforated stem, and an open link engaged with the perforation of the stem of the hook and with the perforation of the outer end of the second plate.

696,979. CONNECTED CROSS-TIE, TRAIL-PARTITION, AND RAIL-JOINT. VINCENT L. KIMMELT, Knoxville, W. Va. Filed Dec. 10, 1901. Serial No. 56,577. (No model.)

Claim.—1. The combination with a cross-tie having a seat formed in the upper face thereof, of overlapping rail-clamping members fitted in the seat and having wedge-shaped overlapping portions, and means to draw the members inwardly in opposite directions and thereby to clamp the same upon a rail and against the opposite sides of the seat.

2. The combination with a cross-tie having a seat formed in the upper face thereof, and provided with an opening through the back of the seat, of a pair of overlapping rail-clamping members fitted in the seat and having wedge-shaped overlapping portions, one of the members being fixed to the tie and the other member which is adjustably secured to the tie in the tie being movable toward and away from the fixed member, and a

wedge-shaped fastening to be driven through the opening and into frictional engagement with the movable member to force the same toward the fixed member and into snug engagement with the adjacent wall of the seat.

3. The combination with a cross-tie having a seat formed therein and opposite openings formed in the back of the seat, of a pair of self-closing rail-gripping members fitted in the seat and having wedge-shaped overlapping portions, one of the members having a lag or projection fitted in one of the openings to prevent accidental endwise movement of the member, and a wedge-shaped fastening to be driven into the other opening in frictional engagement with the other member and thereby force the same toward the fixed member.

4. The combination with a cross-tie having a flanged seat formed therein and opposite openings formed in the back of the seat, of opposite rail-gripping members fitted in the seat with their outer edges lying beneath the flange of the seat and also provided with wedge-shaped overlapping portions, one of the members having a lag or projection fitted in one of the openings to hold the member against movement, and a wedge-shaped fastening driven in the other opening in frictional engagement with the other member to force the same toward the fixed member.

5. The combination with a cross-tie having a longitudinal dovetailed groove formed in the upper face thereof and also provided with opposite openings formed in the back of the groove, of a pair of rail-gripping members seated in the groove and having wedge-shaped overlapping back portions and upstanding endwise rail-engaging shoulders, which have their lower portions cut away at alternate sides to receive the inner end of the other member, one of the members having a pendant lag or projection seated in the adjacent opening to prevent movement of the member, and a wedge-shaped fastening driven in the other opening in frictional engagement with the inner member to force the same toward and into co-operative relation with the fixed member.

6. A track-fastening, comprising a metallic tie having in its under face provided with longitudinal channels to render the tie yieldable, the upper face of the tie being provided with a central longitudinal seat, and said upper face being beveled outwardly and downwardly in opposite directions from the opposite sides of the seat, rail-engaging fastenings fitted in the seat and having overlapping wedge portions, and means for drawing said wedge portions into mutual engagement to form the rail-engaging means into frictional engagement with the opposite sides of the seat.

7. As a new article of manufacture, a solid metallic cross-tie which is substantially triangular in cross-section, the bottom thereof having a pair of longitudinal channels formed therein and providing an intermediate longitudinal rib, the apex of the tie being removed, there being a central longitudinal seat formed in the top of the tie, and the downwardly-inclined portions of the tie at opposite sides of the seat forming longitudinal flanges to be embedded in ballast.

8. The combination with a cross-tie having an opening formed therein, of a fixed rail-clamping member, a movable rail-clamping member co-operating therewith, a headed wedge-shaped pin driven into the opening in the tie and against the movable clamping member, and a pin-locking key inserted in the opening prior to the application of the pin, and clamped between the head of the later and the movable clamp member.

9. The combination with a cross-tie having an opening formed therein, of a fixed rail-clamping member, a movable rail-clamping member, a wedge-shaped pin to be inserted into the opening and against the movable member, and a pin-locking key to be inserted in the opening, the lower end of the key having a toe to underlie the bottom of the tie, and the upper portion of the key having a lateral shoulder to rest upon the top of the tie, and also having a bendable portion which is capable of being bent over against the top of the pin to prevent displacement thereof.

10. The combination with a cross-tie, of co-operating rail-clamping members supported upon the top of the tie and having wedge-shaped overlapping portions, and means to draw the members inwardly in opposite directions and thereby to clamp the same upon a rail.

696,980. SLIDING-DOOR FASTENER. JOSEPH H. KENT and WILLIAM H. ROSS, Harrisburg, Pa. Filed June 26, 1901. Serial No. 66,094. (No model.)

Claim.—1. The combination with a slotted casing, of a rod slidably mounted in the casing, a button thereon, means for imparting longitudinal motion to the rod, and means whereby said button will be projected laterally through the slot in the casing at the beginning of the movement of the rod in one direction and whereby said button will be retracted from the slotted plate at the end of its reverse movement.

2. The combination with a slotted casing, of a rod slidably mounted therein, a button extending from the rod, a stud upon the rod, a casing adapted to receive the rod and having a curved slot engaged by the stud, whereby the button is adapted to be projected through the slot in the casing at the limit of the movement of the rod in one direction, and re-

tracted at the beginning of its reverse movement, and means for imparting motion to the rod.

3. The combination with a casing, of a recessed casing within each end thereof, each casing having curved slots therein, a rod within the casing, studs at the ends of the rod slidably mounted within the curved slots, a button extending from the rod and adapted to be projected through the slot in the casing when said rod reaches the limit of its movement in one direction and to be retracted at the beginning of its reverse movement and means for imparting motion to the rod.

4. The combination with a slotted casing, of a recessed casing within each end thereof, each casing having curved slots therein, a rod, studs extending from the rod and slidably mounted within the curved slots, a button extending from the rod and adapted to be projected through the slot in the casing when said rod reaches the limit of its movement in one direction and to be retracted from said slot at the beginning of its reverse movement, a crank-shaft journaled within the casing, a lever thereon and a link connection between said crank-shaft and the rod whereby motion is imparted thereto from the lever.

5. The combination with a structure having a slotted plate secured thereto, of a second structure, a casing secured thereto, a rod slidably mounted within the casing, a button projecting therefrom, means for imparting motion to the rod and means whereby said button will be projected into engagement with the slotted plate at the beginning of the movement of the rod in one direction and whereby said button will be retracted from the slotted plate at the end of its reverse movement.

6. The combination with a door-casing having plates secured at each side thereof and provided with butt-hole-slots, of a sliding door, a lock-casing secured to each side edge thereof and each casing containing a sliding rod, a recessed casing adapted to receive each end of said rod and having curved slots therein, studs extending from the rod and slidably mounted within the curved slots, buttons extending from the rod, a crank-shaft journaled within the casing, a lever pivoted thereto and a link connection between the crank-shaft and rod whereby motion is imparted thereto from the lever, said buttons being adapted, when the rod is moved in one direction, to project into and slide within the butt-hole-slots and to slide within and be retracted from said slots during the reverse movement of said rod.

696,981. PICTURE-HANGER. GEORGE E. KAY, New Orleans, La. Filed Nov. 12, 1901. Serial No. 36,397. (No model.)

Claim.—A picture-hanger, comprising the extensible handles D and E, the collars F F, secured to said handles D and embracing handle K, the thumb-screw H, for locking the two handles together, the hook N secured to the end of handle E, bent at right angles adjacent to the point where it emerges from the end of said handle, and its shank portion disposed in a plane parallel to the end of handle E, the base bent at right angles over the end of the handle carrying the same, and formed into a hook with the extremity thereof bent to form a spur and in a plane parallel with the length of the handles as set forth.

696,981.

696,982. TIDE-MOTOR. FRANK E. LANTIER, Brooklyn, N. Y. Filed Apr. 12, 1901. Serial No. 55,305. (No model.)

Claim.—1. In a tide-motor, a casing having its upper portion air-tight and provided with a gate or valve-controlled opening in its lower portion, said casing being arranged so that the air contained therein will be compressed by the flow of the tide, and a pipe communicating with the top of said casing whereby the air contained therein may escape, substantially as described.

2. In a tide-motor, a casing provided with a gate or valve-controlled opening in its bottom and arranged so that the lower portion of said casing will be submerged by the rise of the tide, the upper part of the casing being air-tight, and a valve-controlled pipe communicating with the top of the casing to permit the escape of the air therefrom when the valve is opened, substantially as described.

3. In a tide-motor, a casing having its upper portion air-tight and arranged so that its lower portion will be submerged by the rise of the tide, an inlet to said casing, means for opening and closing said inlet, a valve-controlled pipe communicating with the top of the casing to permit the escape of the air therefrom when the valve is opened, and means for opening the inlet when the tide has reached a predetermined height on the exterior of the casing, substantially as described.

4. In a tide-motor, the combination of a casing having an inlet, of a frame in said casing communicating with the inlet and the interior of the casing, and a water-wheel in said frame actuated by the water admitted through said inlet, said water-wheel being movable with relation to the inlet, substantially as described.

5. The combination with a casing provided with an inlet, of an engine, a telescopic frame in said casing communicating with the inlet and the interior of the casing, a turbine in said casing relatively secured to a shaft operatively connected with said engine, said turbine being rotated by the water admitted through said inlet, substantially as described.

6. In a tide-motor, the combination with a casing having an inlet and an outlet, of a frame in said casing communicating with the inlet and the interior of the casing, a rotatable turbine in said frame, and a rotatable turbine in the casing arranged adjacent to the outlet substantially as described.

7. In a tide-motor, the combination with a casing having an inlet, a frame communicating with the inlet and the interior of the casing having its sides comprising one or more telescopic sections, a shaft journaled

in said frame and casing, a rotatable water-wheel keyed to said shaft and movable axially thereon, and means to extend said frame with the rise of the water in the casing, substantially as described.

8. In a tide-motor, the combination with a casing, provided with an inlet and an outlet, of means actuated by the tide for automatically opening and closing the outlet, and means actuated by the tide for automatically opening and closing the inlet when said outlet is closed and for holding said inlet open when the outlet is closed, substantially as described.

9. In a tide-motor, the combination with a casing, provided with an inlet and an outlet, a frame provided with telescopic sides communicating with said inlet and the interior of the casing, a rotatable water-wheel in said frame, means for automatically opening and closing said inlet, and means for automatically opening and closing said outlet, substantially as described.

10. In a tide-motor, the combination of a horizontally-cased casing provided with an inlet and an outlet, a frame in said casing having telescopic sides, a turbine in said frame relatively secured to a shaft journaled in said frame, a turbine arranged adjacent to the outlet and relatively secured to a shaft journaled in the casing, means for automatically closing and opening said inlet and outlet, and an engine operatively connected with the said shafts, substantially as described.

11. In a tide-motor, the combination of a horizontally-cased casing provided with an inlet and outlet, gates for closing said inlet and outlet, means dependent on the movement of the tide for automatically opening and closing the outlet-gate, means dependent on the movement of the tide for automatically opening and closing the inlet-gate when the outlet-gate is closed, a pipe communicating with the top of said casing and having a normally closed valve therein, and means dependent on the movement of the tide for opening said valve, said means being adapted to permit said valve to close before the outlet-gate is opened, substantially as described.

12. In a tide-motor, the combination with a horizontally-cased casing provided with an inlet and an outlet, a pipe communicating with the top of said casing and having a valve therein, means for automatically opening and closing the outlet, means for automatically opening and closing the inlet, means for opening the valve in said pipe while the inlet is open and for closing same before the outlet is opened, and an automatically-actuated valve in the casing for admitting air to said casing to prevent the formation of a vacuum in the casing, substantially as described.

696,983. GAS-CAPSULE. GEORGE A. LOGAN, Chicago, Ill. Filed Feb. 2, 1901. Serial No. 45,512. (No model.)

Claim.—1. A gas-capsule adapted for use in charging or aerating beverages in bottles or other receptacles, said capsule being made of metal and provided with an opening, and a removable and puncturable metal casing-plug inserted and removably secured within said opening, substantially as described.

2. A gas-capsule adapted for use in charging or aerating beverages in bottles or other receptacles, said capsule being made of metal and provided with an opening, and a removable metal casing-plug inserted and removably secured within said opening, said plug being provided with a puncturable diaphragm, substantially as described.

3. A gas-capsule adapted for use in charging or aerating beverages in bottles or other receptacles, said capsule being made of metal and having a plate or disk secured in its open end, said plate or disk being provided with an opening or aperture, and a removable metal coil inserted in said opening, substantially as described.

4. A gas-capsule adapted for use in charging or aerating beverages in bottles or other receptacles, said capsule being made of metal and having a plate or disk secured in its open end, said plate or disk being provided with an opening or aperture through which the gas is forced into the capsule, and a metal casing-plug inserted in said opening, said plug being provided with a head fitting in insertion in said opening, and the plug being provided with a bore or passage which is obstructed or closed by a diaphragm or wall, said diaphragm or wall being adapted and arranged in position to be engaged by a projection on the device to which the capsule is applied, and the plug being readily removable after the gas has been liberated from the capsule, whereby the latter may be refilled and used again, substantially as described.

5. A metallic capsule adapted to contain gas or fluid under pressure and provided with an opening, and a metallic casing-plug inserted in

said opening and provided with a longitudinal bore or passage, said bore or passage being obstructed or closed by a diaphragm or wall adapted to be engaged by a point or projection on the device to which the capsule is to be applied, so as to open the passage through the plug and thereby allow the gas to escape from the capsule, and said plug being readily removable after the gas has been liberated from the capsule, whereby the latter can be refilled and used again, substantially as described.

6. A gas-capsule provided with an opening, a metal plug inserted in said opening and having its inner end expanded or clenched to prevent the pressure of the gas from forcing it out, the said plug being formed with a penetrable diaphragm and being readily removable, so as to permit the capsule to be refilled and used again, substantially as described.

7. A gas capsule formed with arrow-threaded and polygonal portions and with a penetrable end and adapted for use in charging or aerating beverages in bottles, substantially as and for the purpose set forth.

8. A gas-capsule adapted for use in charging or aerating beverages in bottles and having its opening sealed by a removable metal plug having a head limiting its insertion therein and expanded or clenched at its inner end to an extent to properly seal the said opening but not to an extent to prevent the ready withdrawal of the plug for the purpose of permitting a refilling of the capsule.

9. A gas-capsule adapted for use in charging or aerating beverages in bottles and having its opening sealed by a removable plug formed with a head limiting its insertion in said opening and with laterally-projecting portions which prevent the pressure from forcing the plug out of place, substantially as described.

10. A gas-capsule adapted for use in charging or aerating beverages in bottles and constructed with a suitable opening, an abutment or deflecting-surface arranged at the inner end of said opening, a sealing-plug having a headed outer end and a bifurcated inner end, said plug being inserted in said opening and having its said inner end spread or deflected laterally by said abutment or deflecting-surface arranged at the inner end of said opening, substantially as described.

696,984. DISK PLOW. JOHN E. W. LOMB, Hamilton, Ohio, assignor to the Long & Altmeyer Company, Hamilton, Ohio. Filed Feb. 17, 1902. Serial No. 94,364. (No model.)

Claim.—In a disk plow, the combination, substantially as set forth, of a beam, a plow-disk obliquely mounted thereon, a hand-wheel, a furrow-wheel, a beam-head having a pivot-hole substantially in the forward-end line of travel of the disk and having another pivot-hole to the backward of the first-mentioned one, a short tongue adapted to have its rear end pivoted at either of said holes in the beam-head, a furrow-wheel carried by the tongue, steps to limit the swinging of the tongue upon the beam-head, a pivot at the forward end of the tongue, and an overer provided with two holes adapted for alternative pivotal connection with the forward end of the tongue, one of said holes being located at the mid-length of the overer and the other at one third its length from the forward end, said overer being adapted for a singletree at its backward end and for either a singletree or a doubletree at its forward end.

696,985. ENVELOP. JONATHAN LORAN, Charleston, S. C. Filed Nov. 21, 1901. Serial No. 84,365. (No model.)

Claim.—1. An envelop having closed sides and ends, composed of two sections, one of said sections having closed sides and an open end opening into said other section, the sides of said sections having an open-

ing in one of its sides, and an opening in its end communicating with said closed section at one end and a folding-line between the sections whereby material contained in said envelop may be slid into said closed section for self-keeping and into said section having the open side to display the contents of said envelop through said opening.

2. An envelop having closed sides and ends, foldable between its ends and having an opening in one side between the center and one end thereof, whereby two sections are formed, one of which is adapted to contain the contents of the envelop and into the other of which the contents are adapted to be moved to display the same.

3. An envelop having closed sides and ends, a folding-line between its ends and having an opening in its inner side between the fold and one end thereof, whereby an envelop is formed one section of which is capable of containing material and the other section of which is adapted to display the material when the material is moved to that section and means for securing the two sections of the envelop in their folded position.

4. An envelop having closed sides and ends comprising a closed section and a section having an opening in one side thereof, a folding-line between the sections whereby an envelop is formed, one section of which is capable of securely holding the material and the other section of which is adapted to display the material, when the material is moved into that section and means for securing the two ends of the envelop in their folded position.

5. An envelop having closed sides and ends comprising a closed section and a section having an opening in one side thereof, said opening being smaller than said section, whereby an overhanging edge is formed around said opening and a folding-line between said sections, whereby an envelop is formed, one section of which is adapted to securely hold material placed therein and the other end of which is adapted to display without loss the material contained in said envelop, when the same is moved into that section.

6. An envelop having closed sides and ends comprising a closed section and a section having an opening in one side thereof, said two sections communicating, said opening being smaller than said section, whereby an overhanging edge is formed around said opening, and a folding-line between the sections, whereby an envelop is formed, one section of which is adapted to securely hold the contents thereof, and the other section of which is adapted to display without danger of loss the contents when they are moved to that section.

7. An envelop having closed sides and ends comprising a closed section and a section having an opening in one side thereof, said two sections communicating, said opening being smaller than said section, whereby an overhanging edge is formed around said opening, and a folding-line between the sections, whereby an envelop is formed, one section of which is adapted to securely hold the contents thereof, and the other section of which is adapted to display without danger of loss the contents when they are moved to that section, with means for securing the two ends of the envelop to their folded position.

696,986. IMPLEMENT FOR DESTROYING PLANTS. JOHN LUDWIG and JOHN CARSTEN, Newtonburg, Wm. Filed Sept. 27, 1901. Serial No. 76,740. (No model.)

Claim.—In an implement of the character as described, a series of cutting-blades suitably carried, the middle cutting-blade having straight cutting edges, the side cutting-blades having their inner rear cutting edges curved in behind the cutting edges of the middle cutting-blade.

696,987. FURNACE. JOHN HANCOCKMAN, BRYAN, N. J., assignor to Royal C. Fawcett, Brooklyn, N. Y. Filed Dec. 20, 1900. Serial No. 41,022. (No model.)

Claim.—1. In a furnace, the combination with an air-supply bar, of a hallow perforated rotatable tray partially surrounded by said bar but extending out of the same, substantially as set forth.

2. In a furnace, the combination with a magazine and means for forcing fuel vertically upward through the same so that the fuel piles over its side, of a series of hallow rotating grate-bars extending substantially in line with the upper edge of the magazine and onto which the fuel therefrom flows, and a hallow rotary tray interposed between the fuel-magazine and said grate-bar, substantially as and for the purposes set forth.

3. In a furnace, the combination with a magazine and means for forcing fuel upwardly through the same so that the fuel piles over the side of the magazine, of two sets of rotary grate-bars extending substantially in line with said sides and on which the fuel from the magazine flows, and a hallow rotary tray interposed between each side of said magazine and the adjacent grate-bar, substantially as and for the purposes set forth.

4. In a furnace, the combination with a series of rotatable grate-bars arranged side by side, of a toothed bar for engaging said grate-bars, and continuously-operating means for advancing said toothed bar into engagement with the grate-bars, advancing the same to rotate said bars and then withdrawing the toothed bar from engagement with the grate-bars.

5. In a furnace, the combination with a series of rotatable grate-bars, arranged side by side, of a toothed bar for engaging said grate-bars, and a rotating shaft carrying an eccentric for moving said toothed bar into engagement with the grate-bars, advancing the same to rotate said bars, and then withdrawing the toothed bar from engagement with the grate-bars.

696,988. THREAD-CUTTER. ALBERT B. HANMER, Yale, Conn. Filed Aug. 5, 1901. Serial No. 78,000. (No model.)

Claim.—In a thread-cutter of the character described, the combination of two thread-cutting members pivotally connected, a spring to normally force said members apart, a handle extending from one of said members, said handle being provided with a threaded portion and an opening extending transversely through said threaded portion, said remaining member being provided with a projecting ear adapted to pass through said

opening and a wedge-shaped termination adapted to fit into said transverse opening, and a nut upon said threaded portion adapted to engage said wedge-shaped termination, as and for the purpose set forth.

696,989. METHOD OF DRYING HATS. JAMES HANNAH, Fox River, Mass. Filed Apr. 4, 1901. Serial No. 54,381. (No specimens.)

Claim.—1. The method of drying hats, consisting in subjecting the moist hats to a moderate temperature in a confined space, gradually raising the said temperature to a maximum, and simultaneously withdrawing the vapors evolved from the moist hats, substantially as described.

2. The method of drying hats, consisting in subjecting the moist hats to a moderate temperature in a confined space, passing a current of air through the confined space and about the hats therein, increasing the temperature in the confined space by successive uniform stages to a maximum, and removing the hats from the confined space, substantially as described.

3. The method of drying hats, consisting in subjecting the moist hats to a temperature at or about 100° Fahrenheit, withdrawing the vapors evolved from the hats by a current of air, condensing the vapors from the current of air, and simultaneously increasing the temperature in the confined space by successive uniform stages to a maximum of 130° or 140° Fahrenheit, substantially as described.

4. The method of drying hats, consisting in surrounding the moist hats by a body of air at a moderate temperature in a confined space, withdrawing this air and the vapors evolved from the hats, condensing the vapors from the air as withdrawn, replacing with dry air the portions of air withdrawn, and gradually raising the temperature of the body of air surrounding the hats by successive uniform stages to a maximum, substantially as described.

696,990. SPINNING DEVICE. GEORGE W. HERRICK and ADOLF HERRICK, Hartford, Conn., assignors to Frederick C. Packard, West Hartford, Conn. Filed Apr. 17, 1901. Serial No. 54,384. (No model.)

Claim.—A spinning device consisting of a frame-like handle, a spindle extending through and rotarily held by portions of the handle and having its outer end threaded, a spirally-twisted elastic connection between the inner end of the spindle and the end of the handle, and a cord attached to and wound about a portion of the spindle for rotating the spindle against the twist of the elastic connection, substantially as specified.

696,991. DOD-GEED. JOHN C. MYERS, Centerville, Mich. Filed Oct. 19, 1901. Serial No. 79,330. (No model.)

Claim.—1. The combination with a sled, having brackets secured thereto, of a guard comprising a body portion and a front, said front being upwardly turned and cut out to permit of the draft appliance being attached to the draft-bar, means for attaching said front to the draft-bar, and slotted cleats secured transversely to said body portion.

2. As an article of manufacture, a sled-guard comprising a body portion, an upturned front having a central opening and secured to the body portion, and a transverse cleat provided with a draft attachment.

3. The combination with a sled, of L-shaped brackets secured to the cross-bars thereof, a guard, and cleats transversely arranged on the guard and having slots through which extend the horizontal members of said brackets to secure the guard in position.

696,992. HOLLOW SEAMLESS RUBBER ARTICLE. THOMAS W. MILLER, Akron, Ohio. Filed Jan. 29, 1902. Serial No. 91,903. (No model.)

Claim.—1. As an article of manufacture, a hollow rubber article having a narrow elongated open neck or stem formed integral therewith and projected into the interior of said article, substantially as set forth.

2. As an article of manufacture, a hollow rubber article having a narrow elongated open neck or stem formed integral therewith and projected into the interior of said article, the walls of said neck or stem substantially contacting and adapted to be cemented together to close said opening, substantially as set forth.

696,993. MUSE-RACK. BENJAMIN W. HILL, Boston Harbor, Mass. Filed Feb. 1, 1900. Serial No. 4,309. (No model.)

Claim.—1. A music-rack comprising a central plate having members pivoted thereto and spaced inwardly from the ends thereof, additional members slidably connected with the first members for movement to lie thereover to fold therewith over the central plate, plates pivoted to the outer ends of the second members for movement therewith to lie over the central plate, flanges upon the lower members, the flanges of the lower members terminating short of the central plate, and clips mounted upon the end portions of the central plate beyond the pivoted members, the lower clip being adapted for movement inwardly between the flanges and beyond the members to engage music upon the members, the upper clip being slidably mounted for movement toward and away from the flanges.

2. A music-rack comprising a central plate having arms pivoted thereto for movement to lie thereon, additional arms slidably connected with the first arms to lie thereon, and plates pivoted to the outer ends of the second arms for movement therewith to lie over the central plate, and music-holding clips pivoted upon the outer plates for movement to project therebeyond or to fold to lie thereon and longitudinally thereof.

3. A music-rack comprising a central plate, arms pivoted to the plate for movement to lie thereon, and the lower arms having supporting-flanges, said plate extending beyond the upper arms, and means connected with the extension of the plate for holding music upon the rack, said holding means being adjustable toward and away from the supporting-flanges.

4. A music-rack comprising a central plate having supporting-arms pivoted thereto for movement to lie thereon, said plate extending beyond the arms and having a slot therein, and a music-holding clip slidably engaged with the slot of the extension to hold music upon the rack.

696,994. ELEVATOR. AUGUST H. MOORE, Brooklyn, N. Y. Filed Apr. 10, 1901. Serial No. 65,139. (No model.)

Claim.—1. The combination with an elevator-wall; pairs of vertical rows of rollers journaled upon the walls thereof near the corners of said wall, one row of each pair having its journals arranged at right angles to the journals of the other row of the same pair; of a carriage adapted to move in said wall; vertical screws journaled upon said carriage, and each screw adapted and arranged to engage the rollers, in both rows of one of said pairs of rows; and mechanism for actuating said screws, to move said carriage, substantially as shown and specified.

2. The combination with an elevator-wall; pairs of vertical rows of rollers journaled upon the wall thereof, one row on each side of a corner thereof, near said corner, and arranged so that the journals of the row on one side of the corner will be at right angles to the journals of the row on the other side of the corner; of a carriage adapted to move in said wall; vertical screws journaled on said carriage, and each screw adapted and arranged to engage the rollers in both rows of one pair of said rows of rollers; an electric motor fastened on the bottom of said carriage; mechanism connecting said motor with said screws, whereby it is enabled to turn said screws, and move said carriage; and connections whereby said motor is supplied with an electric current, all substantially as and for the purpose set forth.

3. The combination with an elevator-wall; pairs of vertical rows of rollers journaled upon the wall thereof, one row on each side of a corner thereof, near said corner, and arranged so that the journals of the row on one side of the corner will be at right angles to the journals of the row on the other side of the corner; of a carriage adapted to move in said wall; vertical screws journaled on said carriage, and each screw adapted and arranged to engage the rollers in both rows, of one of said pairs of rows of rollers, an electric motor mounted upon the bottom of said car-

ribs and moving therewith; mechanism comprising shafts and wheels, as specified, connecting said motor with said screws, and enabling it by turning said screws to move said carriage; an electric generator, conductors connecting said generator with said motor; and means for controlling the electric current flowing from said generator in said motor; all substantially as and for the purpose set forth.

686,995. HANDLE FOR A NUMBER OF IMPLEMENTS. THOMAS G. HONER, Elm College, N. C. Filed May 4, 1901. Serial No. 53,713. (No model.)

Claim.—A handle adapted to contain a number of implements having the front and back edges parallel and the sides from about the center to near the rear ends transversely projected and parallel, and a straight partition-strip extending centrally through the handle from end to end and parallel with the major portions of the sides.

686,996. PORTABLE HOUSE. CHARLES F. HOTT, Elbert, Pa. Filed Apr. 23, 1901. Serial No. 57,666. (No model.)

Claim.—1. In a portable house, the combination of wall-boards laid longitudinally and having beveled ends, corner-uprights into which the beveled ends of the wall-boards are inserted, and means for connecting said uprights, whereby close joints are formed at the corners and the wall-boards held against lateral displacement, substantially as set forth.

2. In a portable house, the combination of wall-boards arranged to form miter-joints at the corners, rectangular corner-uprights within which the miter-joints are formed, and means for connecting said uprights, substantially as set forth.

3. In a portable house, the combination with the wall-sills, walls and roof-boards, of uprights secured to the sills for securing the wall-boards, said uprights having projections extending above the roof-boards, and tie-boards extending across the roof-boards for securing the uprights together and for holding down the roof-boards, substantially as set forth.

4. In a portable house, the combination with wall-sills, walls, and roof-boards, of uprights secured to the sills for securing the wall-boards, said uprights having projections extending through slots in the end roof-boards, and tie-boards extending across the roof-boards and provided with slots through which said projections also extend, and means for securing said tie-boards in position, substantially as set forth.

5. In a portable house, the combination of wall-sills A, B, having mortised joints, the tenons b of sill-pieces B projecting through sill-pieces A, corner-uprights consisting of rectangular pieces having mortised extensions c engaging tenons b, said uprights securing the wall-boards in position, and extensions d projecting above the roof-boards, tie-boards extending across the roof-boards and mortised to said uprights, and means for securing the mortised joints, substantially as set forth.

6. In a portable house, the combination of wall-sills A, B, having mortised joints, the tenons b of sill-pieces B projecting through sill-pieces A, corner-uprights consisting of rectangular pieces having mortised extensions c engaging tenons b, said uprights securing the wall-boards in position, and extensions d projecting through slots in the end roof-boards, tie-boards extending across the roof-boards and provided with slots through which said extensions d also extend, and means for securing all joints, substantially as set forth.

7. A door-sill for portable houses, consisting of a sub sill cut to fit wall-boards having beveled ends and having means for holding it in position, and a slotted top sill, the projections formed by the slots at both ends extending on opposite sides of the wall-boards, substantially as set forth.

8. A door-sill having in combination separable interlocking jamb, hotel and sill pieces, substantially as set forth.

9. A door-sill having in combination separable interlocking jamb, hotel and sill pieces, and said jamb-pieces being interchangeable and reversible, whereby a door hung to either of the jamb-pieces may be arranged to swing in different directions without rearranging the hinges on the jamb, substantially as set forth.

10. In a portable house, the combination with the walls, of a roof formed of separable tongue-and-grooved boards, said tongues and grooves being provided with interlocking means to prevent relative longitudinal movement of the boards, substantially as set forth.

686,997. SIFTER. JOSEPH E. MYLLER, Oak, Ill. Filed July 11, 1901. Serial No. 57,397. (No model.)

Claim.—1. In a sifter, the combination with a body; of a sieve arranged therein and provided with an upwardly-extending throat; a sectional top arranged upon said body and embracing the throat of the sieve, the sections of said top being provided with upwardly-extending flanges having overhanging ribs; a cover fitting beneath said ribs and provided with a hopper registering with the throat of the sieve, and a reel journaled in the sieve.

2. In a sifter, the combination with a body; of a sieve arranged therein and comprising a pair of sections hinged together; said sieve being provided with an upwardly-extending throat; a reel journaled within said sieve; a top arranged upon said body and embracing the throat of the sieve, said top being provided with a pair of upwardly-extending flanges having overhanging ribs; and a cover arranged beneath said ribs and provided with a hopper registering with the throat of the sieve.

3. In a sifter, the combination with a body; of a sieve arranged therein and formed of hinged sections, a sectional top carried by the casing and embracing the sieve and serving to hold the sections together and a reel in said sieve.

4. In a sifter, the combination with a body; of a sieve arranged therein and formed of hinged sections, the upper ends of said sections forming a throat, a sectional top carried by the body and embracing the throat of the sieve whereby the hinged sections are held together, and a reel in said sieve.

5. In a sifter, the combination with a body; of a sieve arranged therein and formed of hinged sections, the upper ends of said sections forming a throat, outwardly-extending lugs to the throat, a sectional top arranged upon said body and embracing the throat of the sieve whereby the sections thereof are held together, the sections of said top being provided with notches adapted to receive the outwardly-extending lugs carried by said throat and support the sieve, and a reel in said sieve.

6. In a sifter, the combination with a body; of a sieve arranged therein and comprising a pair of sections hinged together, a reel arranged within said sieve, and a top upon the body embracing and supporting the sieve and adapted to hold the hinged sections together.

7. In a sifter, the combination with a body; of a sieve arranged therein and comprising a pair of sections hinged together, said sieve being provided with an upwardly-extending throat, a reel journaled within said sieve, and a top arranged upon the body and embracing the throat of the sieve and adapted to support the same and hold the hinged sections together.

8. In a sifter, the combination with a body having a slot at each end; of a sieve arranged within said body and formed of hinged sections, a reel journaled within said sieve, a shaft thereto extending through said slots, securing-blocks arranged within said slots and fitting upon said shaft, and a top arranged upon the body and removably secured thereto, said top engaging the sieve and adapted to support the same and hold the hinged sections together.

696,998. NUT-LOCK. NORMAN J. HOLMAN, West Bay City, Mich. Filed Oct. 4, 1901. Serial No. 77,699. (No model.)

Claim.—1. A nut-lock comprising an internally-threaded elastic washer, having a slit extending from the periphery to the threaded hole; together with a key inserted in said slit to hold its edges normally apart, said key having a parallel-sided upper portion and a blunt wedge-point, substantially as described.

2. A nut-lock comprising an internally-threaded polygonal spring-washer having a slit extending from the periphery to the threaded hole, the sides of said slit being normally wedged apart; together with a wedge adapted to be released from the washer, by contact with the nut to be locked, when the washer is screwed down upon the nut, substantially as described.

696,999. GRAIN-FLOW INDICATOR. CHARLES C. BRALL, Minneapolis, Minn. Filed June 10, 1901. Serial No. 62,562. (No model.)

Claim.—1. The combination with a hopper or grain-receptacle having a discharge-opening in its bottom, of an indicator or compass at the exterior of the hopper, and an actuator for said indicator located within said hopper, near the bottom thereof, and in the vicinity of the discharge-opening thereof, which actuator has a connection to said indicator and is subject to the flow of the grain in the discharging action, substantially as described.

2. The combination with a hopper or grain-receptacle, of an indicator or compass, and a pair of independently-movable indicator-actuators located within said hopper and subject to the outward flow of the grain therefrom, both of which actuators have connections for action on said indicator, substantially as described.

3. The combination with a hopper or grain-receptacle, of a compass pivoted at the exterior thereof, and an actuator for said compass comprising a pivotally-mounted blade with connections to said compass mounted within said hopper, in the vicinity of the bottom discharging-opening thereof, substantially as described.

4. The combination with a hopper or grain-receptacle, of a compass pivoted at the exterior thereof, a pair of independently-movable actuating-blades pivoted within said hopper in the vicinity of the bottom discharge-opening thereof, and flexible connections between said actuator blades or members and said compass, substantially as described.

5. The combination with a hopper 1, of the flattened shield a, tubular connections extending from the said shield a to the side of the hopper, the compass g pivoted to the exterior of said hopper, the independently-mounted chases f having exposed blades f', the flexible connections k attached to the hub of said arm g' and provided at the lower end with the strands h connected, one to each of the chases f, and sub-

stantially as described.

6. The combination with a hopper or grain-receptacle having a discharge-opening in its bottom, of an indicator or compass at the exterior of said hopper, a pivoted or hinged actuating-blade mounted within said hopper, near the bottom thereof, and in the vicinity of this discharge-opening, and a flexible connection between said actuating-blade and said indicator, substantially as described.

697,000. APPARATUS FOR APPLYING RUBBER TIES TO VEHICLE-WHEELS. JOHN BRANT, Kokomo, Ind., assignor to the Kokomo Rubber Company, Kokomo, Ind., a Corporation of Indiana. Filed June 2, 1901. Serial No. 62,524. (No model.)

Claim.—1. A machine of the character described, comprising a bed-plate, two sets of wire clamping or holding devices thereon, a ratchet-bar mounted to slide on the bed-plate tangentially to the wheel and provided with a wire-gripping device, and a tension-lever pivotally connected with the bed-plate and provided with a pawl to engage the ratchet-bar, substantially as described.

2. A machine of the character described, comprising a bed-plate, two sets of wire clamping or holding devices thereon, a ratchet-bar mounted to slide on the bed-plate tangentially to the wheel and provided with a wire-gripping device, a tension-lever pivotally connected with the bed-plate and provided with a pawl to engage the ratchet-bar to move the same in one direction, and a detent to prevent movement of the bar in the opposite direction, substantially as described.

3. A machine of the character described, comprising a bed-plate, two sets of wire clamping or holding devices thereon, a ratchet-bar mounted to slide on the bed-plate tangentially to the wheel and provided with a wire-gripping device, a tension-lever pivotally connected with the bed-plate and provided with a pawl to engage the ratchet-bar to move the same in one direction, and a series of detent-pawls of differing lengths to prevent movement of said bar in the opposite direction, substantially as described.

4. A machine of the character described, comprising a bed-plate, two sets of wire clamping or holding devices thereon, a ratchet-bar mounted to slide on the bed-plate tangentially to the wheel and provided with a wire-gripping device consisting of a fixed jaw having legs, a movable jaw guided by said legs, a pivot-bolt connecting said legs, and a cam mounted on said pivot-bolt and provided with a hand-lever, and a tension-lever pivotally connected with the bed-plate and provided with a pawl to engage the ratchet-bar, substantially as described.

5. A machine of the character described comprising a bed-plate having wire holding or clamping devices, a bracket mounted on said bed-plate and having a pair of upstanding legs at each end, a pivot-bolt connecting each pair of legs, a tension-lever mounted on one of said bolts and having a pawl, a detent-pawl mounted on the other bolt, and a ratchet-bar provided with a gripping device and sliding between the legs, substantially as described.

6. In a machine of the character described, a wire-clamping device comprising a body having an extension forming the fixed jaws, pivoted levers provided with the movable jaws and having inclined ends, and a disk having a screw-thread and operating between the inclined ends of the levers, substantially as described.

7. In a machine of the character described, a wire holding or clamping device comprising a yoke having a projection extending in one direction and forming the fixed jaws, and a threaded extension in the opposite direction, a disk mounted on said last-mentioned extension and having a feeding device engaging the thread thereof, and levers pivoted on opposite sides of the yoke and having the movable jaws at one end, and inclined bearing-surfaces for the disk at the other end, substantially as described.

8. A machine of the character described, comprising a dotted bed-plate, a tension device mounted thereon, a dotted bracket straddling the dot of the bed-plate, and wire holding or clamping devices mounted at each end of the bracket, substantially as described.

697,001. INSULATOR. WILLIAM E. FIDELLA, Birmingham, VI., assignor of one-half to Elmer E. Larrabee, Birmingham, VI. Filed Dec. 8, 1901. Serial No. 84,922. (No model.)

Claim.—1. An insulator composed of interchangeable members, both members being freely reversible, and each member substantially cylindrical and cut away at one side to form a shoulder having a V-shaped groove at its inner terminal and an outer similarly-shaped groove at a higher elevation than the former groove and provided with a series of transverse corrugations, a table extending upwardly from the shoulder at an angle of inclination and dividing the member into two parts, and interlocking projections disposed on opposite sides of the table, the latter having a central vertically-disposed opening extending therethrough.

2. An insulator composed of interchangeable and reversible members each of which is formed with upper and lower grooves, and a central upwardly-inclined table with an opening therethrough, interlocking projections being disposed on opposite sides of the table and having inverted-V-shaped apices.

3. An insulator composed of interchangeable and reversible members, each member having upper and lower grooves with transverse corrugations, and an intermediate groove of V-shaped form, a central upwardly-inclined table intersecting the intermediate V-shaped groove and having an opening extending vertically therethrough, and projections rising from the member at opposite sides of the table and provided with inverted-V-shaped apices.

4. An insulator composed of interchangeable and reversible members, said members having transversely-corrugated grooves at different elevations adapted to coincide with similar structures, an intermediate groove, and projections extending upwardly on opposite sides of the center, and having terminals to engage the said intermediate grooves.

5. An insulator composed of interchangeable and reversible members, said members having transversely-corrugated grooves at different elevations adapted to coincide, intermediate grooves in the said members, and interlocking devices on one side of the intermediate grooves.

697,002. COMBINATION TELEPHONE INSTRUMENT. JAMES S. BOLAN, Chicago, Ill. Filed Aug. 7, 1901. Serial No. 71,318. (No model.)

Claim.—1. A self-contained, combination telephone instrument comprising a base, a generator mounted on said base, a call-bell and indu-

tion-coil mounted on said generator, a switch-hook mounted on said base, and terminal binding-screws on said base for each element of said combination, substantially as set forth.

2. A self-contained, combination telephone instrument, comprising a base of insulating material, a current-generator mounted thereon, a switch-hook mounted on an extension of said base, an induction-coil supported between the magnets of said generator, a call-bell ring supported by said magnets between the poles thereof and said induction-coil and terminal binding-screws on said base for each element of said combination, substantially as set forth.

697,008. AIR-BRAKE. JOHN E. FURMAN, Watertown, N. Y. Filed May 4, 1900. Serial No. 15,488. (No model.)

Claim.—1. In an operating-valve, the combination with a valve-casing having a plurality of ports, and a valve therein adapted in its movement to open and close said ports, of a rotatable operating-head adapted in its movement axially to operate the said valve, a removable handle adapted in its engagement with and disengagement from the rotatable operating-head at a certain predetermined intermediate position thereof, and a spring, one end of which is secured to a fixed support and the other end of which is adapted to rest against a fixed support during a movement of the said operating-head in one side of its said predetermined intermediate position and to be carried by the said operating-head during its movement to the other side thereof.

2. In an operating-valve, the combination with a valve-casing having a plurality of ports, and a valve therein, adapted in its movement to open and close the said ports, of a rotatable operating-head adapted in its movement axially to operate the said valve, a coil-spring, one end of which is secured to a fixed support and the other end of which is adapted to rest against a fixed support during a partial movement of the said operating-head and to be carried by the said operating-head during another part of its movement.

3. In an operating-valve, the combination with a valve-casing having a plurality of ports, and a valve therein, adapted in its movement to open and close the said ports, of an operating-head adapted in its movement axially to operate the said valve, a coil-spring one end of which is secured to the said casing and the other end of which is adapted to engage with a projection in said casing during a partial movement of the operating-head and to be picked up and carried by a projection on the operating-head, during another portion of its movement.

4. In an operating-valve, the combination with a valve-casing having a plurality of ports, and a valve therein, adapted in its movement to open and close the said ports, of a rotatable operating-head adapted in its movement axially to operate the said valve, a removable handle adapted to engage with the rotatable operating-head, locking mechanism whereby the valve may be automatically locked in an intermediate position upon the removal of the handle and a spring arranged to return the valve to such intermediate position from its movement in one direction, said spring arranged to have the valve free to move in either direction upon the opposite side of said intermediate position.

687,004. FILLING-REPLENISHING LOOM. JONAS NORTHER, Hopdale, Mass., assignor to Draper Company, Hopdale, Mass., a Corporation of Maine. Filed July 2, 1901. Serial No. 67,437. (No model.)

Claim.—1. In a loom, the lay, an automatically self-threading shuttle adapted to contain a supply of filling, a normally inoperative actuator mounted on the shuttle and having a finger transverse to the path of and automatically engaged by the filling when a fresh supply is inserted in the shuttle, and a body adapted to project laterally beyond the shuttle side when breakage or exhaustion of the filling releases the finger, filling-replenishing mechanism, to insert a supply of filling in the shuttle and means to control its operation, including a dagger pivotally mounted on the lay and having a part in the path of the actuator-body when the latter is operative, to move the dagger into operative position by the shuttle as it reaches the end of its throw.

2. In a loom, the lay, a shuttle, a filling-carrier therein with a supply of filling, a normally inoperative actuator mounted on the shuttle, controlled by the filling-thread between the filling-carrier and the shuttle-eye and movable into operative position by breakage or exhaustion of the filling, filling-replenishing mechanism, located at one side of the loom, and means to control the operation of said mechanism, including a dagger mounted on the lay at the end adjacent said mechanism, the actuator when operatively positioned engaging and rendering the dagger operative by the completion of the shuttle movement into the adjacent shuttle-box, and a dog moved into active position by the dagger at each time as the lay beats up.

3. In a loom, the lay, a shuttle adapted to receive a supply of filling, a device at one end of and to thread the shuttle automatically when filling is inserted, an actuator mounted on the shuttle adjacent the threading device and automatically engaged and normally held inoperative by the filling while intact, mechanism to automatically insert a supply of filling in the shuttle, and means to control its operation, including a dagger mounted on the lay and having a part in the path of the actuator, if operatively positioned by or through breakage or exhaustion of the filling, engagement of the dagger and actuator rendering the former operative when the shuttle has been completely beamed.

4. In a loom, the lay, an automatically self-threading shuttle adapted to contain a supply of filling, an actuator on the shuttle, having its outer end movable in a slot in the side wall of the shuttle and automatically engaged and maintained in inoperative position by the filling while intact, a filling-feeder, a transferer, means to operate it to transfer a supply of filling from the feeder to the shuttle, said means including a normally inoperative dog, and positioning device for the dog, actuated by or through the actuator when in abnormal, operative position, as the shuttle completes its throw and is properly beamed at the end of the lay adjacent the filling-feeder.

5. In a loom, the lay, an automatically self-threading shuttle adapted to contain a supply of filling, a filling actuator mounted on the shuttle and having its inner end extended across the filling-thread and automatically engaged thereby upon entrance of a fresh filling-supply, and having its outer end extended through an opening in the shuttle side, said actuator being maintained inoperative by the intact filling, filling-replenishing mechanism at one side of the loom, to insert a fresh supply of filling in the shuttle, a shuttle-box on the adjacent end of the lay, having an aperture in its front wall, and controlling means for the said mechanism, including a dagger pivotally mounted on the lay and having a foot extended through the aperture in the shuttle-box wall, the actuator when released by breakage or exhaustion of the filling engaging the foot as the shuttle reaches the end of its throw, thereby turning the dagger into position to cause the operation of the filling-replenishing mechanism as the lay beats up.

6. In a loom provided with filling-replenishing mechanism, means for controlling its operation, including a dagger on the lay, and a dog having an arm to be engaged by the dagger to operatively position the dog, the lay, a bumper thereon to engage the dog when operatively positioned, and effect operation of the filling-replenishing mechanism on the

forward beat of the lay, a shuttle adapted to contain a supply of filling, and an actuator mounted thereon and maintained inoperative by intact filling, release of the actuator causing it to engage and operatively position the dagger as the shuttle reaches the end of its throw at the same end of the lay.

7. In a loom, filling-replenishing mechanism located at one side of the loom, means to control its operation, including a dagger mounted on the lay at the end thereof adjacent said mechanism, a take-up, the lay, a shuttle adapted to contain a supply of filling, an actuator mounted thereon and maintained inoperative by intact filling, and means, to prevent operation of the take-up, including a movable bumper mounted on the lay at the end furthest from the replenishing mechanism, the shuttle when properly beamed at the replenishing side of the loom acting through the actuator if the latter is in operative position, to move the dagger to effect actuation of the replenishing mechanism on the same pick, and to prevent the operation of the take-up when the shuttle is properly beamed at the opposite end of the lay.

8. In a loom, filling-replenishing mechanism located at one side of the loom, means to control its operation, take-up mechanism, the lay, a shuttle adapted to contain a supply of filling, and devices to suspend normal operation of the take-up mechanism and permit let-back, actuated by or through proper boxing of the shuttle at the outer end of the lay, if the filling fails or is exhausted, the proper boxing of the shuttle, under the same conditions, at the inner end of the lay, adjacent the replenishing mechanism, effecting the operation of the controlling means to cause the actuation of the filling-replenishing mechanism.

9. In a loom, a stop-motion therefor, filling-replenishing mechanism, means to control the operation thereof, take-up mechanism, the lay, a self-threading shuttle adapted to contain a supply of filling, an actuator carried by the shuttle and maintained inoperative by intact filling, the actuator when in operative position cooperating with the controlling means to effect actuation of the replenishing mechanism as the shuttle reaches the end of its stroke in one direction, a device to cooperate with the actuator when operatively positioned, as the shuttle completes its stroke in the opposite direction, to suspend the operation of the take-up mechanism, and means operative by or through two successive operations of said device to effect the actuation of the stop-motion for the loom, whereby the loom will be stopped automatically if the shuttle fails to thread after the operation of the filling-replenishing mechanism.

10. In a loom, filling-replenishing mechanism, means to control the operation thereof, take-up mechanism, including a let-back pawl, means to suspend the operation of said mechanism and permit the let-back pawl to operate, said means including an arm having a detent and a latch-bumper thereon, a shipper, a knock-off lever therefor, a latch normally held inoperative by the detent, means controlled by operation of the let-back pawl to release the latch from the detent and move the former into position to actuate the knock-off lever, after the first operation of the take-up-suspending means, a shuttle adapted to contain a supply of filling, and an actuator carried thereby and normally maintained inoperative by intact filling, the actuator when released by filling failure cooperating with the controlling means to effect filling replenishing as the shuttle reaches the end of the stroke in one direction, said actuator, when operatively positioned, effecting the operation of the means for suspending action of the take-up as the shuttle completes its stroke in the opposite direction, the successive operation of said take-up-suspending means moving the arm thereof to bring the latch-bumper into engagement with and to move the latch and thereby the knock-off device to release the shipper.

687,005. SELF-THREADING LOOM-SHUTTLE. JONAS NORTHER, Hopdale, Mass., assignor to Draper Company, Hopdale, Mass., a Corporation of Maine. Original application filed July 2, 1901, Serial No. 67,437. Divided and this application filed Feb. 13, 1902. Serial No. 33,374. (No model.)

Claim.—1. A loom-shuttle having an elongated opening there-through to receive a supply of filling, and a slot in its side wall, a device

at one end of said opening to automatically effect the threading of the shuttle, an actuator movably mounted on the shuttle within said opening and extended laterally through the slot, and a finger on the actuator extended transversely of the shuttle, and normally engaged and depressed by the filling adjacent the threading device to maintain the actuator in inoperative position.

2. A loom-shuttle having a slot in its side wall, and a delivery-eye, a device to automatically thread the shuttle, a fixed downhold adjacent said device, and an actuator pivotally mounted on the shuttle and extended through the slot, said actuator having a finger movable between the downhold and the threading device, the filling in its passage from the filling-carrier to the threading device passing under the downhold and over the finger, to retain the actuator inoperative while the filling is present or intact.

3. An automatically self-threading shuttle adapted to contain a supply of filling, and having a slot in its side wall, an actuator mounted on the shuttle and having a finger transverse to the path of the filling, said actuator having a body portion projecting through the slot in the side wall of the shuttle, and adapted to project laterally beyond the side, when free to move, the filling normally engaging and depressing the finger, and thereby maintaining the actuator in inoperative position.

4. An automatically self-threading shuttle adapted to contain a supply of filling, and having an opening in its side wall, a tilting actuator mounted on the shuttle and having its inner end extended across the path of and adapted to be automatically engaged by the filling-thread, and depressed thereby upon insertion of a supply of filling into the shuttle, the outer end of the actuator extending into the opening in the shuttle side, the action of the filling upon the inner end of the actuator depressing the same, and elevating its outer end to thereby render the actuator inoperative while the filling is present.

5. In an automatically self-threading shuttle, adapted to contain a supply of filling, a threading device, a tilting actuator mounted on the shuttle adjacent the inner end of said threading device, said actuator having its inner end extended transversely across and to be engaged and depressed by the filling-thread between the filling supply in the shuttle and the threading device, the inner end of the actuator being extended through an opening in the side wall of the shuttle, the thread while intact maintaining the actuator tilted with its outer end in inoperative position.

697,008. FIRE-REVERSING APPARATUS. CHARLES HUBERT, Cincinnati, Ohio. Filed Nov. 22, 1901. Serial No. 52,497. (No model.)

Claim.—1. A base device embodying in combination a stud adapted to be affixed to a wall or vertical support, a central roller pivoted upon the stud, and a fixed vertical plate or guide to retain the base in a roll between itself and the wall upon the roller operating upon the stud.

2. A base device embodying in combination a stud adapted to be affixed to a support, a central roller pivoted upon the stud, and a fixed vertical plate or guide to retain the base in a roll between itself and the support, said plate or guide being of substantially Y shape and having its side edge serving as a guide for the paying-out portion of the roll as the roll diminishes.

3. In a base device of the character indicated, the combination of a stud adapted to be affixed to a wall or support, a roller mounted upon the stud and having its periphery partly removed or recessed to admit the light of a doubled or folded base, and a vertical plate or guide fixed to the stud and serving to retain the base in a roll between itself and the wall.

697,007. CONTROLLING ARC-LAMPS. BURAGE GILLEY, Brooklyn, N. Y., assignor to the General Electric Company, a Corporation of New York. Filed Aug. 28, 1900. Serial No. 23,000. (No model.)

Claim.—1. In a system of electrical distribution, the combination, with a supply-circuit, of a plurality of translating devices in operative re-

lation thereto, a magnetically-operated circuit-controller in a ground branch of the supply-circuit, controlling the several translating devices, a switch operated by said circuit-controller to cut in and out the several translating devices, a second ground branch of opposite electrical potential at the control station, and a switch for opening and closing said branch.

2. In a system of electrical distribution, the combination with a supply-circuit, of a plurality of translating devices in operative relation thereto, a magnetically-operated circuit-controller in a ground branch of the supply-circuit for the respective translating devices, a switch operated thereby to cut in and out of circuit the respective translating devices, a second ground branch of opposite electrical potential at the control station governing the circuit-controller, a switch governing said branch, and an electric indicator in the control-circuit at the control station.

697,008. REVOLVING SNOW STAND OR RACK. HENRY F. PALMER, Lynn, Mass. Filed Mar. 26, 1901. Serial No. 53,124. (No model.)

Claim.—1. A revolving display-rack, having, in combination, a revolving carrier, a fixed support therefor, shelves rotatably mounted in the carrier, a driven sprocket-wheel rigidly connected to each shelf, a driving sprocket-wheel rigidly mounted upon the fixed support, the driving and the driven sprocket-wheels having the same number of teeth, and a single sprocket-chain connecting the driving sprocket-wheel with each driven sprocket-wheel and passing over the driving and the driven sprockets in the same direction, substantially as described.

2. A revolving display-rack, having, in combination, a revolving carrier, a fixed support therefor, shelves rotatably mounted in the carrier, a driven sprocket-wheel rigidly connected to each shelf, a driving sprocket-wheel rigidly mounted upon the fixed support, the driving and the driven sprocket-wheels having the same number of teeth, an idler sprocket-wheel, a single sprocket-chain leading from the driving sprocket-wheel to each of the driven sprocket-wheels in succession and thence to the idler and back to the driving sprocket-wheel and passing over the driving and the driven sprockets in the same direction, substantially as described.

3. A revolving display-rack, having, in combination, a revolving carrier, a fixed support therefor, shelves rotatably mounted in the carrier, a driven sprocket-wheel rigidly connected to each shelf, a driving sprocket-wheel mounted upon the fixed support and normally held from movement thereon, the driving and the driven sprocket-wheels having the same number of teeth, a single sprocket-chain leading from the driving sprocket-wheel to each driven sprocket-wheel in succession, and thence back to the driving sprocket-wheel passing over the driving and the driven sprockets in the same direction, and means for adjusting the driving sprocket-wheel upon the fixed support, substantially as described.

697,009. ELECTRIC TELEPHONE SYSTEM. WILLIAM H. FENSTER, Wittenberg, Wis. Filed Dec. 24, 1900. Serial No. 60,572. (No model.)

Claim.—1. An electric telephone system having a spring-contact and an opposing contact-point normally separated at each station, a telephone-receiver and a local battery in circuit with said contact and point, a one-way ratchet-wheel operative against the spring-contact, the tilting-lever for said receiver, and means for holding the lever in normal position when said receiver is removed therefrom, whereby intermittent momentary interruptions of current from said battery occurring incidental to rotation of said wheel against said spring-contact are then audible in the aforesaid receiver.

2. An electric telephone system having an audible signal at each station thereof arranged to influence a transmitter, and means for actuating the signal simultaneously with the opening and closing of the talking-circuit at the same station, whereby when the signal is made it will be heard in receivers connected on the line.

3. An electric telephone system having an audible electric signal in normally open circuit at each station thereof arranged to influence a transmitter, and means for making and breaking said circuit simultaneously with the closing and opening of the talking-circuit at the same station, whereby when the signal is made it will be heard in receivers connected on the line.

4. An electric telephone system embodying tilting-levers each provided with a shouldered arm constituting a circuit make-and-break device, an electric audible-signal device in a local circuit having terminals in the path of said lever-arm and a telephone-transmitter arranged to be influenced by the signal device.

5. An electric telephone system including a switchboard, an electric audible-signal device, the transmitter of a switchboard-telephone arranged to be influenced by the signal device, and means for energizing said signal device simultaneously with closing and opening of talking-circuit at the switchboard, as well as for preventing open signal being given while the talking-circuit is closed at said switchboard.

6. An electric telephone system comprising a switchboard, an electric audible signal at the switchboard in a local circuit electrically connected to the line, a transmitter arranged to be influenced by the signal device, switchboard-plugs electrically connected in pairs and likewise connected with the signal-circuit, spring-contacts insulated from each other to constitute a brush in said signal-circuit, a contact-arm movable on an arc of a circle to operate as a circuit-closer in conjunction with the brush, and a gravity swing-stop having the upper end thereof arranged in the path of said arm, this end of the stop being made with a right-angle notch facing in a direction away from the aforesaid arm when the latter and said stop are in normal position, whereby there is no interference of one with the other on swing of the arm from normal position to pass the brush, but engagement of said arm in the stop-notch preliminary to recontact with said brush on reverse movement.

697,010. MUD-GUARD FOR VEHICLES. JACOB FRIEDMAN, Rochester, N. Y. Filed Nov. 20, 1901. Serial No. 24,112. (No model.)

Claim.—A mud-guard for vehicles, comprising screw-threaded socketed rods with apertures to fit over the axle of a vehicle, said rods being offset outwardly from the apertured portions, a frame consisting of legs and a pivoted head, the legs being formed with collars and the ends of the legs being fitted in the sockets with the collars bearing against the ends of the rods, and cup-shaped couplings secured on the said legs and engaged with the collars and secured on the ends of the rods, all substantially as shown and described.

697,011. SELF-FEEDING MECHANISM FOR METAL-POTS. JOHN FLAEG and WARREN J. LOWE, Broadheath, England, assignors to the Mergenthaler Linotype Company, New York, N. Y. Filed Dec. 21, 1900. Serial No. 60,527. (No model.)

Claim.—1. In combination with a linotype-machine, a magazine adapted to receive and loosely hold a column of uniform type-metal blocks, mechanism for removing the blocks one at a time from the bottom of the column and permitting them to fall into the pot below, and intermediate driving mechanism adjustable to vary the frequency of said delivering action in relation to the speed of the machine, whereby predetermined and uniform additions of metal may be made to the body of metal in the pot at longer or shorter intervals as demanded.

2. In combination with a linotype-machine a magazine having a plurality of upright chambers each adapted to carry a series of uniform blocks of type-metal, and mechanism substantially as described, arranged to deliver the blocks successively from one chamber, and thereafter successively from the succeeding chamber to the melting-pot.

3. The combination of the first vertically-channelled magazine, the single-ported plate thereover, an intermediate rotary magazine provided with a ratchet-wheel, mechanism for alternately locking and unlocking said ring, and an actuating-pawl connected with and operated by a linotype-machine.

4. In combination with the reciprocating metal-rod of a linotype-machine, an upper fixed magazine having a series of vertical channels, an underlying rotary ring or plate having a single port, mechanism connected with a linotype for rotating said ring step by step, that its ports may register with the overlying magazine chambers, an intermediate or secondary magazine underlying and provided with chambers corresponding in number with those in the upper magazine, a ratchet-wheel connected with the intermediate magazine, a pawl for operating the same, and adjustable connections between said pawl and the linotype for imparting to the pawl a variable movement.
